No. The license is for operating, not building. Anyone can build whatever equipment they want with no license at all, but to put it on the air legally requires a license.

> >Actually I don't think the 5 wpm Morse Code test was too much to ask.
> >But that's ancient history now.
>
> Is that the old 'weeder' reason or the old 'I had to do it' reason?

Neither. It's the "reasonable requirement to know what you are doing" reason.

The basic argument against the code test comes down to this:

Why should anyone have to learn it if they don't intend to use it? Those who want to use it will learn it on their own, and those who don't will learn it and not use it.

That same argument can applied to almost anything in the written tests, though.

For example:

Why should anyone have to learn about VHF/UHF if they only intend to use HF?

Why should anyone have to learn about solid-state if they only intend to use tubes?

Why should anyone have to learn about FM, SSTV, RTTY, etc., if they only intend to use CW, AM or SSB?

Why should anyone have to learn about theory if they only intend to use manufactured gear?

Why should anyone have to learn about RF exposure safety if they only intend to use low power?

Etc.

What happens is that the argument, taken to its logical conclusion, says there should be no real test at all. FCC tried having a radio service with no test - it didn't work out too well.

The designer of this power supply did something very wrong.
Using the safety/chassis ground as a power connection to
run 120V loads is dangerous. If you need to power 120V
loads run a neutral line or use a 240/120 transformer.

Safety ground should only be connected to the chassis,
faraday screens and Y-rated capacitors.

Neutral and safety ground eventually tie together so
it seems like an OK thing. It's not. It's a violation
of the NEC, any applicable safety standards and might
on the off chance cause serious injury or death.

I've tried both, and the 7360 wins by a long way - it probably proves
that "you get what you pay for"! The 7360 gave me useful conversion gain,
a spectacularly high intercept, and as low a noise figure as you could ever
wish for.

That's true, but the Swan transceivers weren't using the 7360 as a receiving mixer. They were using it as the balanced modulator in the transmitter section, which is a very different job, and the 6JH8 was a low-cost alternative.

The 6JH8 could probably be used (with mods) in a lot of SSB transmitter projects from the hollowstate era, rather than the 7360.

What circuit and values did you use, Bob? Voltages, balanced vs. unbalanced, output and input circuits, etc.?

N2EY@aol.com wrote:

>AJ Lake <nom...@fakeaddress.com> wrote:

>I do have a [treaty] source. [3 listed]

But if the treaty had not required a code test for the 220 MHz Tech in the license change of 1951, do you think the hams of the day (both inside and outside the FCC) would have allowed a codeless ham to exist? It would have been scary to even express those thoughts aloud in those days, considering what you hear now, 50+ years later...

>> I haven't been an ARRL member since the dark days.
>When were these "dark days"?

Incentive Licensing. I have always voted with my wallet.

>The license is for operating, not building.

The Technician was meant for those who were more interested in VHF/UHF experimentation than HF operating.

>The basic argument against the code test comes down to this:
>Why should anyone have to learn it if they don't intend to use it?

I've heard that argument, but that's not why they quit the code test.

The reasons for a code test that once applied are no longer valid. No more military CW. No more ship to shore CW. No more WW2 ops needed. Ect ect ect. CW is now really obsolete for anything but hobby use. Making involuntary human modems has little value to the government any more.

>What happens is that the argument, taken to its logical conclusion,
>says there should be no real test at all.

The ham test should be about *modern* technology. Testing about past obsolete technology and practices such as tubes, mechanical RTTY, and code ect just doesn't make sense.

Gee, if you don't plan on using the ham license, why bother taking a test?

An old Tech class Elmer that first taught me the code, told me you need it so you will know what repeater you are talking on.   I find Morse code useful but I can see how someone who doesn't know it might not find any use for it. Even I can't tell you what it's good for if you don't plan on using it. DUH.

I still have some Vinyl records and even a couple of 45s still. I like some Classical music too even though the people that wrote it are dead, I guess that makes it obsolete. So what's with these Heavy Metal bands where they are still using a Tube guitar amp and half of those guys have one foot in the grave anyway. Even the newest bands are old guys in their 30s with 15-20 year olds freaking all around them. Except for the Girl bands all but doing strip shows. That's kind of entertaining, but everytime they open their mouths, bubble gum and bullsqueek comes out. But then you have all these teen girls who idolize them and dress like strippers and everyone wonders why their teen daughters have all gone astray, but NOOO, they tell us we're OLD and don't know what were talking about because all their girlfriends are pregnant and had 15 abortions when they were 15, so why can't they have fun too. Just because they say the 50 yo migrant worker is cute and says he loves her, why can't she have him for a sleepover. ARGGGGHHE... but I digress. What is it with these NEWBIES telling us - We who know better - That Morse Code is useless.

I'll tell you one thing, E-mail isn't even faster than Morse Code. In fact they should do away with E-mail because it's slower than Morse Code. The fact that someone actually marketed a Blackberry smaller than a full size keyboard must have been tasked to find out how many idiots there are trying to push their lives through a microscopic keyboard when a Straight key you don't even have to look at to find the alphabet. Shouldn't cell phones have made them all obsolete? Come to think of it, these computers should be obsolete too because they are so much slower than cell phones. Or maybe because you can't even talk to people on the phone anymore because they are stuck sifting through their SPAM lists.

Just a few Wild-A** thoughts.

```

Hi,

Just the pin or the cap?

I use finishing nails for the pins as I usually break them getting them out :-\

If it's the little inner plastic cap thing, heatshrink tubing is a nice fix.

Cheers.

--
Gregg

>I still have some Vinyl records and even a couple of 45s still.

Hopefully you still have the antique/obsolete equipment to play them.

>I like some Classical music too even though the people that wrote it
>are dead, I guess that makes it obsolete.

Classical music isn't obsolete. But the technology used to store it
can be obsolete (such as wire spool recording) or modern (such as
computer mp3 files).

>So what's with these Heavy Metal bands where they
>are still using a Tube guitar amp...

Tube guitar amps are supposed to sound better. Hard for me to tell
with all that intentional distortion they introduce into the music.

My old *tube* receivers still work fine even though they're antiques
(and quite obsolete). But in serious QRM/QRN I have to switch to my

modern rig with the receiver digital processing if I want to complete the QSO.

> We who know better - That Morse Code is useless.

CW is *not* useless. It's fun. It's all I ever use these days. Unfortunately the phone bands are often R rated so I left there years ago. CW is still a gentlemans band and great place to enjoy the CW *hobby*...

N2EY@aol.com wrote:

> What circuit and values did you use, Bob? Voltages, balanced vs.
> unbalanced, output and input circuits, etc.?

Balanced throughout! Supply is 130 V, and the deflection plates have a 10 k preset (to give DC balance) with the wiper going to the supply, and the ends connected to potential dividers (68 k and 10 k) to give 15 V at pins 8 and 9. The anodes are connected directly to the primary of a 10.7 MHz IF transformer, with the centre tap of the transformer going to the positive rail through a 220 ohm resistor. There is a fixed capacitor (of 100 pF) from one anode to ground, and the other anode has a parallel combination of 68 pF fixed and a 65 pF trimmer to ground to allow phase balance. Pin 3 (grid 1) has - 1.9 V bias fed through a 470 k resistor and is coupled to the top of an at-frequency tuned circuit - the high input impedance of the valve allows the tuned circuit to be connected without a tap. The bias line has to be well-decoupled (I used a 470 uF electrolytic) to prevent hum. The control grid (pin 2) is connected to the positive supply through a 470 ohm resistor, and is decoupled to ground with 10 nF.

The balanced local oscillator (a pair of 2N3819 FETs) is buffered by a pair of common emitter bipolar transistor stages (I used 2N3866, because I have a lot of them) and fed to the deflection plates in antiphase. IF rejection is roughly 60 dB, conversion gain is 25 dB. You can tune right through the IF frequency /without/ /a/ /whistle/ - which is unique in my experience!

I found the circuit values in the original valve specification, and they seem to be well optimised - I tried various alterations, but always to the detriment of performance.

The Kallitron oscillator is stabilised (in 10 Hz steps) with a huff-and-puff unit based on a PIC, which also provides a frequency readout on an LCD display.

Over the years, I've tried /every/ possible mixer topology, including the modern H-mode switching types (which are astonishingly good), but the 7360 can't be beaten.

The receiver is simply the best that I've ever used, even including some of the high-priced exotica that I saw and used at the BBC Caversham Monitoring department!

Bob

Yeah its a fool killer, Did you notice how they develop the Vcc.
 Im sure under the conditions
its designed to be used its safe enough but if you get enough
 hams tinkering with it someone might get killed.
David Smith kind of backed out of the project because of this.

I got sidetracked on this project a bit remodeling my bathrooms
but while prowling through my storage shed(junk box) I came across an
```

old SMPS, it s rated 48 volts at 50 amps. I was going to build a
big FET amp around it but never did. The output of it is just
rectifiers and filters connected to the transformer. There
is a second winding that is rectified and appears to develop
feedback voltage. I was thinking of building a step up transformer
and connecting it back to back with the transformer on
this power supply. I was also having thoughts of just replacing the
transformer with one designed for HV.

They generally do. They introduce concordant (even order) harmonic
distortion, so are nicer to listen to.

> My old *tube* receivers still work fine even though they're antiques

> (and quite obsolete). But in serious QRM/QRN I have to switch to my

My valve (tube - U.S>.) receivers far out-perform /any/ semiconductor
receiver. I don't need any digital processing at all.

>> We who know better - That Morse Code is useless.
>

I can "work the world" on tiny power using CW, whereas I'd have to use
stupid amounts of power to get similar results with SSB. Also, the people
you meet on CW tend to be much more friendly!

C.

Hi Bob

A lot of folks have reported good results using the 6JH8 in place
of the 7360; with a few reporting better linearity. They appear
to be pretty much the same as far as performance. Have you tried
one?

Pete

Yes I have. The results were disappointing compared to the 7360. Perhaps
my values weren't optimised. Maybe I should try again - the 6JH8 is /much/
cheaper!

Bob

Your tube receivers outperform *any* semiconductor (solid state - U.S>.) receiver? I guess that would mean in all ways. That's a big claim. What receivers might those be?

>I don't need any digital processing at all.

Ah, I'm getting the picture now. You are firmly rooted in the past. Not unusual with old timers. The problem often is that we think everyone else should be the same. That's why it took so long to kill the code test.

>I can "work the world" on tiny power using CW, whereas I'd have to use
>stupid amounts of power to get similar results with SSB.

Less power needed is an advantage of CW. Also less antenna needed. I run 50 watts to a random wire 8' high (HOA stealth antenna) with quite satisfactory results. It's not a DX antenna, though I do snag one every now and then. CW ragchewing's my game, and I seldom fail to complete a QSO.

>Also, the people you meet on CW tend to be much more friendly!

Yes CW is a gentlemans band.

Yes. In every way. Intermodulation, noise floor, selectivity, ultimate sensitivity, every parameter you can think of! The receivers were very carefully designed and constructed by me, (though taking advice from some of the "classic" designs), and have been widely tested against some really serious, exotic receivers!

>>I don't need any digital processing at all.
>
> Ah, I'm getting the picture now. You are firmly rooted in the past.

Not at all. I'm a professional electronics designer, and use the very latest technology when applicable. I haven't seen /any/ digital processor that assists me in actually picking signals out of QRM. I'd rather use tight filtering (RF, IF and AF), and synchronous demodulation when needed. The real trick is a receiver with extreme selectivity (not the bogus pseudo-selectivity given by digital filters with all their nasty artifacts) and a really low noise floor.

> Not unusual with old timers. The problem often is that we think
> everyone else should be the same. That's why it took so long to kill

Absolutely not - I'm happy for you if you're happy with your digital Rice Box - I'd rather use something *I* made and get results that often astonish my friends and colleagues.

>>I can "work the world" on tiny power using CW, whereas I'd have to use

I have a loop over my garden (backyard - U.S.), which is (just) resonant on 7 Mhz and has a reasonable match on other bands. It's basically two long wires above each other, connected by a vertical section at the far end and with a transformer coupling at the house end (the transformer is 6 metres of UR 67, and the horizontal sections are about 9 metres long). It's not the world's greatest antenna, but works surprisingly well for its small size.

> It's not a DX antenna, though I do snag one every now and then.

Me too!

> CW ragchewing's my game, and I seldom fail to complete a QSO.

My latest game has been working on a /really/ simple and cheap frequency synthesiser and SSB generator that's not too critical in component values and easy to align. It's entirely digital!

>>Also, the people you meet on CW tend to be much more friendly!
>

Which completely proves the point that resistance is not futile. That

having the patience to learn a skill will in fact tend to protect a valuable resource from degradation by being flooded with impulsive personalities.
The mentality that wants the FCC rules changed so that they can play music, false signals, profanity, deliberately interfere and act out in public, can't really petition for that, but they can petition to make it easier to have that capability and let nature take it's course.

If you only tested your tube receiver against *some* receivers then
your claim about outperforming *all* SS receivers would be invalid.
'Absolute' statements will get you in trouble most of the time.

>I haven't seen /any/ digital processor
>that assists me in actually picking signals out of QRM.

You not having seen any doesn't mean there aren't any.

>pseudo-selectivity given by digital filters with all their nasty artifacts)

Selectivity is not usually my problem. With close neighbors and a low
wire antenna, it's man made noise that is my problem. Digital does
well with this.

>I'm happy for you if you're happy with your digital Rice Box

Yes we have hams here that are also 'Rice Box' prejudiced. Prejudice
for everything produced in Asia is silly these days.

I've tried them against the *very* *best* receivers available today, and
they win in /every/ respect. They're actually hybrid receivers - I happily

use semiconductors where they're more appropriate (like in synchronous demodulators, audio filters, audio amplifiers, local oscillators and so on), but the really crucial parts - the RF amplifier, first mixer, IF amplifiers and product detectors all use bottles.

There's one crucial parameter that's carefully omitted by most manufacturers, which is the behaviour of their receivers in the presence of strong adjacent frequency interference. The intermodulation, de-sensing and other disasters inherent with semiconductor designs mean that I'll get better results /every/ time.

I've designed /commercial/ solid-state receivers, and there's just *no* *way* to get results as good as can still be obtained from valves in crucial parts of them!

>>I haven't seen /any/ digital processor
>>that assists me in actually picking signals out of QRM.
>
> *You* not having seen any doesn't mean there aren't any.

I've tried most of the stuff on the market, and /none/ of it can really enhance a truly good receiver. They /might/ compensate for the obvious shortcomings of some of the more average receivers!

>>pseudo-selectivity given by digital filters with all their nasty

I'm in the happy situation that I don't suffer from too much of that, despite living in a city (London). There are some really effective noise-cancelling methods that have been published over the years - one approach I used successfully in my old QTH was the counterpoise method that was published years ago in RADCOM.

>>I'm happy for you if you're happy with your digital Rice Box
>
> Yes we have hams here that are also 'Rice Box' prejudiced.

I'm not prejudiced at all - as soon as Far East Asia produces something even half as good as I can build, I'll save time and effort and buy them! In the interim, I'll continue with what I consider to be the real essence of our hobby, and build the gear myself!

> Prejudice for everything produced in Asia is silly these days.

Not at all - they /still/ can't make a good mobile phone! 8-)

Yeah, and I had a shot at a sleeve of them for 60 bucks several months
back :(Unfortunately, they aren't going to get any less expensive as

time passes.

Pete

Sure it does. You can't keep all the nuts out but you could make a big dent in the problem. The fact that so many nuts were whining and crying to be let in was proof of that. Some figured ways around the system. A VE team around here got busted selling licenses. Took their licenses away and called everyone in to retest elsewhere or lose their license too. Most of them got booted out. Yay!

Some of the nuts just blew a head gasket and learned from the other monkeys. Monkey see monkey do. Birds of a feather flock together. I suppose you think the fact that the nonsense is worse now is just society imploding It would probably be even worse but I suspect the only thing in the way of complete animal regression was Riley and the Ham Call Sign. If everybody quit using callsigns though there would be a bloodbath. They have the technology now to get a fix within a few seconds. If there were ever a push it would be an easy roundup. When they got tired of that they would just outlaw ham radio entirely. Up till now they have only made a real effort when vital services are jeopardized. They don't really consider ham radio a vital service anymore because ham radio is losing credibility.

Maybe you can think of some test or hoop besides CW to discourage the people that act out like morons because they lack self-control.

The biggest issue is manufacturing costs. DSP can do a few neat tricks, but most of those were doable with analog circuits. DSP also adds to the noise floor. What they are really doing is saving money on quality physical components like filtering. I had my TS2000 right next to my TS830 and the 830 sounded so much better I almost took the 2000 back. There seemed to be some high frequency noise that I really couldn't hear but I could sense it and it gave me a headache after a while. It actually FELT noisy. It wasn't until I hooked it up to my SP230 that I honestly couldn't tell the difference in the audio and performance of the 830 and all was well. BUT the TS830 had better adjacent frequency performance because of the 8 pole crystal filters. I would still have that radio but I had to move and made the choice for general coverage. I still have a TS130, and I use that at Field day to swap out those new high dollar big shot radios that can't hack the signal overload. It seems the TS130 uses Bandpass filters in the front end, injection and exciter stages in addition to the 8 pole crystal filters.

There are RF tubes that can do up to 10 meters with plenty of gain and much better overload capabilities than what's out there now. It might cost a fortune to use that quality of filtering in a general coverage receiver, but you COULD build a really first class hybrid that blows away what's out there.

The rest of the transceiver industry (other than you) apparently thinks tube embedded HF transceivers are quite obsolete for a wide variety of reasons. Else they would be manufacturing and selling them. Even ham magazines print mostly solid state articles using modern solid state parts, which is right since hams should learn to use modern technology. When they do print a tube article it's usually described as nostalgia.

>I'm not prejudiced at all -

You used the term "Rice Box" to describe your dislike of a whole range of several hundred ham tranceivers. Different manufacturers. Different models. Pure prejudice. Logically you should judge equipment on its individual merits, not by the race of the people who made it.

>I'll continue with what I consider to be the real essence of

>our hobby, and build the gear myself!

Building is but *one* facet of the hobby. Professional engineer hams capable of designing and building transceivers are a but very very tiny part of the hobby...

>Not at all - they [Asians] /still/ can't make a good mobile phone! 8-)

As I said prejudiced...

In the 50s some hams I knew not only used ham radio
as a hobby but actually got paid for working CW, either aboard
ship or at coastal commercial radio stations. I had the CW
(and technical) skills at the time to be considered for employment.

So as I said I've worked CW since 57 but only as a hobby...

So obsolete means there is no commercial or consumer application that
immediately comes to mind, or does it mean that it is fun to do???

So the word "obsolete" is a subjective word reflecting your own usage.
Could something be obsolete if it was old but was better suited to your
application? Or does that make your application obsolete? Is the
automobile obsolete because of air travel? Is rail transportation obsolete
because of trucks? Does obsolete most often refer to something you don't
want someone else to use? Is the word "obsolete" obsolete because too many
definitions have become attatched to it?

> >OK WHICH DIGITAL do you use.

> Head copy.
> > how are you going to make the contact that is gone in 60 seconds
> I'm not. I prefer CW ragchewing. Different strokes...

Bingo! Now what of the guy that has called CQ two or three times and goes
away?
Head copy is the only way to pounce on the contact before they QSY or
someone else picks them up.

It means YOUR BRAIN might not be obsolete after all!!

If it's off-topic enough that you know to change the subject,
then take it elsewhere.

I should have posted last night before all the other carpetbaggers
came out of the woodwork, but foolishly hesitated.

You have no history here, yet you pounce the minute someone posts
about CW, someone who has been here a long time. And then a bunch
of others suddenly appear, even though they don't post about building
amateur radio equipment here.

There is rec.radio.amateur.policy and rec.radio.amateur.misc and even rec.radio.amateur.moderated where you can have your debates to your heart's content. And surely you and the other carpetbaggers would fit in better there, since you don't have anything to say about building radios.

This is not the first time you pouncers have landed here. The last time I remember it happening, the one idiot even cross-posted his reply to rec.radio.amateur.antennas, even though the topic fit neither newsgroup. I didn't read the newsgroup for a month after that, even though I've been reading and posting here for over a decade.

It's idiots like you that kill the newsgroups, seeing offtopic posts as perfectly fine, while those who want to talk about what the newsgroup is about slowly disappear.

Keep the trash out of here, you and the other carpetbaggers.

   Michael VE2BVW

Tim Shoppa <shoppa@trailing-edge.com> wrote:

>The controversy in the 70's was the Technician license, a ticket that
>required no code,

Interestingly in the 50s the Technician (and Novice) was given by mail. And any ham friend could give you the code test. Anyone else could proctor your exam and certify that you were honest. However I'm sure it won't surprise you to learn that there were many Techs who never took a code test and had open book exams.

I always wondered why if the Tech was an experimenters license as the FCC claimed it was, why they required a code test.

The Tech was a very popular license, especially in the late 50s when we had the best sun spot peak on record. I had a modest Globe Scout 680 with about 20W out on 6 meters to a 5 element Taco beam up about 30' , AM of course. The Rx was a war surplus BC455 (7$ brand new mail order) and an International Crystal 6 meter converter. The Tx was crystal controlled so you called CQ and then tuned the lower band for an answer. The band was open stateside every day and my state count on 6M was in the 40s before I got my General and moved to 10M which was even better. DX openings were often and my country count was in the 50s. That was indeed a fun time...

Ah, another net cop with no delete key.

>You have no history here, yet you pounce the minute someone posts
>about CW, someone who has been here a long time.

I've been in these groups since the early 90s. I used to identify
but had a bad experience with a net cop.

> And then a bunch
>of others suddenly appear, even though they don't post about building
>amateur radio equipment here.

Off topic happens. Heck they're talking God stuff in the
antenna group. Why aren't you complaining there?
And who's it hurt anyway? It's not like this place is
flooded with posts every day.

>There is rec.radio.amateur.policy

Right. The kooks have taken over rrap with their profanity and
other sick stuff. That was a fun group some years back

>It's idiots like you that kill the newsgroups

No I think the name calling and net cops are the ones who drive
people away, so keep it up and you will get your wish. In the
meantime just be cool and the thread will die a natural
death, they always do...

"JB" <nospam@goofball.net> wrote:

>So the word "obsolete" is a subjective word reflecting your own usage.

Yes the word obsolete is very subjective. And it "obsolete" means different things to different people. My posts here are my *opinion*. You have stated that you have a different opinion. We have a discussion. That makes it interesting and is why we are all here.

>Head copy is the only way to pounce on the contact before they QSY or
>someone else picks them up.

Yes for contest or DX operation. But for relaxing CW operation a computer can do just fine. Some of my recent QSOs have been with people who admittedly don't know CW and are using a computer. I don't mind as we are both having fun.

>It means YOUR BRAIN might not be obsolete after all!!

My brain is becoming very obsolete in recent years,
very scary...

Au contraire mon ami; most of the replies include descriptions of homebrew
efforts relating to license classes and FWIW, I recognize most of the
respondents as previous posters to this N.G. I for one have appreciated
this discussion.

Regards,

Michael

rec.radio.amateur.policy was destroyed almost single-handedly by one
individual.  Although others made it somewhat of a sewer, he put it into the
coffin and drove the nails and buried it.  I've deleted that newsgroup from
my list entirely as it is completely useless now.

Ok, this should work. http://tinyurl.com/6at4zu

> I mean the primary of this thing uses litz wire that looks like 10AWG
> wire about 13 turns around the core
> and they using 4 strands of 28 AWG to run the filament
> The HV secondary measures only 6.8 ohms DC.

I'm glad you mentioned that. If the core is ferrite and it's gapped, then the litz makes sense to reduce eddy current losses from the fringing field sprayed out of the gap. A gapped core would also most likely mean it is a flyback.

It really is amazing the power density SMPS can achieve. Though the overload capacity available from big hunks of iron and copper isn't to be discounted lightly. I had to pick up a 10KW autotransformer today. I don't know how much it weighed but I'd guess 130lbs, or there about. The two transformers in the 10KW SMPS are maybe four pounds total.

I concur from experience in 1982 when I got my Tech license. I had to
take the 5WPM code test at the FCC office. We had the same HF
privileges as Novices and could operate on any frequency above 50.000

MHz. I can't recall, but I "THINK" the first code-free Tech licenses
did not have HF privileges. Now that there is no code requirement for
any class, I think Techs have some HF privileges again...a bit confusing ;)

>
> The Commission has solicited comments relative to that circumstance, and I hope the following will be considered in that act.
>
> First of all, I would like to wholeheartedly approve of the concept of reducing the number of Amateur License classes from six to four. There is much confusion as to "who's who" as it is now, and a reduction in the licensing process would alleviate that disparity. As such, I envision the following as being appropriate for said restructuring:
>
> Amateur Class D: The Amateur Class D license would become the de facto "entry class" license for the Amateur Service. In light of the grossly decreased demand for the Novice License and reduced useage of the sub-bands allocated for thier use, I would deactivate it as the "entry class" licenese. The Class D License would for all intents and purposes be the same as the current "Codeless Technician" class license. The examination for this license would remove questions pertaining to HF (1.8 to 30 MHZ) theory and operation, and be strictly limited to matters pertaining to VHF/UHF theory and operation, regulatory matters and Amateur practice. All Amateur privileges above 30 MHZ would be conveyed to the successful applicant.
>
> Amateur Class C: The Class C license would be the entry level license for operation on the HF spectrum. It would require the successful applicant either hold a Class D license, or successfully complete the Class D examination in

> addition to an examination on basic HF theory, propagation and practice.

Wow, guess it must really suck to be Steve, or anyone who agrees with him
on the Morse code issue. Or you.

http://www.screedbomb.info/coosn/
Q: Who is eligible for a COOSN?

A: Kookologists with 10 or more verifiable UV points may exchange these points for a Cabal Obsidian Order Sombrero Number.

Q: Who is *not* eligible for a COOSN?

A: Certified net.kooks; notorious net.cretins; terminally clueless fuckwits; previous winners of kook-awards, unless an official pardon has been granted by the FNVW.

Q: How do I apply for a COOSN?

A: Make a Usenet post to alt.usenet.kooks (crossposting to your favourite newsgroups is acceptable); to ensure that the FNVW actually sees your request, try to use either of the following formats for the subject line:

[COOSN Application] Your name (or best known handle) here
[COOSN Request] Your name (or best known handle) here

Please provide a list of 10 UV points - along with verifiable evidence for each point wherever possible.

Q: Can one Kookologist nominate *another* Kookologist for a COOSN?

A: Yes, but the proposer should supply a verifiable list of 10 UV points for the nominee at the time of the nomination. Also, the nominee must accept the nomination before a COOSN is issued.

Q: What happens if my Sombrero Number application is refused by the FNVW?

A: The Office of Darth Bawl is always looking for new candidates. Nuff said.

Q: What are "UV points"?
1. Threats of violence, especially death. (one point per kook)
2. Lists, i.e. *real* lists, not just mentions of two or three names in

the same post. One list per kook, unless the lists are clearly meant to
serve different purposes.
3. Fanboi sites (one point per kook, not one point per site. Minimum
qualification is a whole page about you; pages containing lists don't
score extra if the list also appears on Usenet).
4. Fanboi newsgroups (one point per kook, not one point per group)
5. Attempts at real-life contact (e.g. posting phone numbers)
6. Fake awards, revenge nominations etc. (one point per kook)
7. Mentions in a newsgroup FAQ (e.g. soc.men).
8. Being the target of a Kooksuit (one point per kook).

Gerald C. Newton is a wife-beating fuckhead.

yes he was calling to make the license more complex at a time when the
FCCmade it clear it wanted and was going to have a simpler licensing
scheme

Scott <acepilotREMOVE@bloomer.net> wrote:

> I think Techs have some HF privileges again...a bit confusing ;)

I was happy when they gave the Technician Class License HF CW privileges because I thought that it would help the sagging numbers found on the CW bands. Currently they have the same CW privileges as the General Class on 80, 40, and 15M HF bands.

I hang mainly on 80 and 40 CW and average a couple of QSOs a day. To this date I have yet to contact a Tech. (I check QRZ.com when making entries in my computer log.) So at this point it doesn't seem to have increased CW activity as much as I had hoped.

BTW using the internet makes QSOs even more interesting. QRZ.com often has blurbs and photos of the guy you just talked to. Also using Google Maps you can pinpoint his location, and often using Google Streets you can even see a photo of his house. Amazing.

Hey mule

Exactly right it is a gapped core. Once I git's a scope on I'll see.

But the voltage doubler they using is full wave doubler. Which means
they taking the positive and negative waves  to get 4000 or so volts
DC
Now the positive half they use a .0082 mfd for a filter and the
negative half they use a .0056 mfd filter both at 3000wvdc.
.
They use a damper diode that looks like a varistor, and a hold down
cap is .032 mfd at 500V across the primary.
The power into the primary is filter by an LC just to prevent the RF
getting back into the mains/bridge diodes pack.

i checked the components characteristics .seemed to be two diodes on

one chip.replaced it with two smt diodes and it works.
thanks for all your advice.

I hate Google Streets. It would seem to be an invasion of privacy for
someone to go around taking pictures. The only use is if you are trying to
buy or sell a house. Or plotting a crime. My PO box is on my license.
Perfectly legal since it gets sent out all over the World

I went from Novice to Advanced, having failed the 20wpm the first time. I
still loved to hang on 40 CW, 2 and 440 FM for years. Then 40 got taken
over by broadcasters. I'm a little bit of everywhere now. With 2 m SSB
becoming popular, I've found cross mode CW/SSB actually works, so more
people find it useful than let on. I had talked to some tech+ on 10 SSB/CW.

Many people feel this way.

>The only use is if you are trying to buy or sell a house.

As I said I use it to see where my contacts live. On occasion I even get to see the tower and/or antennas. I used it scope out my old neighborhoods in the Chicago area where I lived as a kid. Also recently I was recently able to scope out a good parking lot on the beach at Pacific Beach CA (and actually able to read to read the parking sign hours) prior to driving there. So I find lots uses for it.

>My PO box is on my license.

If somebody really wants to find you they can. If you give your call it would be duck soup to find where you live, even using a PO box. But even posting anonymously here on Usenet we can be found. The best advice is not to make anyone mad enough to want devote the resources and time it requires to do it.

> I still loved to hang on 40 CW

Maybe we have QSOed in the past. My computer log goes back to 1990. Unfortunately my paper logs are long gone. Give me your call and I'll check..... ;-)

Interesting announcement on the ARRL web site. They have put online an archive of QSTs from 1915 to 2004. If you are a member you can search for and download as a pdf any article without additional cost.

Just for fun I found the article from January 1956 that described my first transmitter.
John

my guess is the quasi-push pull output is due to the leakage energy recovery circuit. HV flyback transformers usually have very high leakage inductance (the part of the magnetizng inductance not coupled to the secondary is leakage inductance) because distance between windings is a major cause of poor coupling and you need distance for isolation.

The leakage energy sloshes about in the primary causing all sorts of mischief. This circuit recovers it and dumps it back into the primary. It's unusual since the leakage energy is usually dumped back into the bulk storage capacitor on the primary side if it's recovered by a clamp winding or active clamp circuit.

A soft switching topology often uses the leakage inductance to reduce transistion losses in the switch. Sometimes a discrete inductor is added in series with the transformer primary to add to it. Another bonus for the lousy coupling of the HV flyback transformer... no discrete inductor needed. I think of this as electronic ju-jitsu.

The energy per half cycle (on the secondary) won't be equal so juggling the capacitor values helps equalize the voltage stress.

Eh! I might be completely wrong. Simulating it would be the thing but it's too much like work work and I'd need the transformer parameters.

At least that's how I think it works... Please let me know when you've scoped the waveforms.

The schematic I sent to msg actually refers to it as a flyback
circuit.
I am guessing one of the IGBTs is being used as a damper.

Exactly right I was in a hurry to get off to work and cut out the part
about the Damper diode and hold down capacitor. So yeah the diode
which looks like a varistor and may very well be a varistor, is the
push pull switch shorting out the induced trailing edge energy of the
IGBT. They use a .032 mfd across the primary along with the damper.
So the damper is switching on after the IGBT turned is off.

Hopefully on the day 911, I get this powered up with low voltage. .
VK3HZ waveforms were at 50 hz trace sweep frequency so you couldn't
see the 30khz waveform.

Many thanks.  I build a lot of valve kit and QST was full of ideas in
the 50's and 60's.  I buy back issues when I see them at hamfests but
you don't often see them in the UK.

Cool, way cool!

I have roughly several hundred often moldy issues of QST's on my
shelves from the 40's through the 70's. Maybe the basement will smell
a little better now that I don't need them :-).
```

Having QEX online would be nice too... (hint, hint).

The sure way the ARRL can keep me as a member is to continue offering
this service to their members!

Did anyone get "QST: Annual Index" to pull up the annual index for any
issue of QST? Returns nothing here _and_ it also highlights (selects)
the "QEX: Annual Index" and "Ham Radio: Annual Index" entries.

And, why no "QST: Table of Contents"!!

It's easy to trawl through various _columns_ in QST. But, unless you
have a pretty good idea what the title is, or who the author was,
there's no easy way to locate a feature article.

I would assume the _intent_ of putting all this up on the ARRL web site
is for ARRL Members to find material in old issues of QST. Why doesn't
the _implementation__ demonstrate this? At least give us the Annual
Index(es) and the TOCs.

I have about 80 years worth of the QST on CD collection. The tool I
use is the ARRL Periodicals Archive and Search
http://www.arrl.org/members-only/qqnsearch.html

> If somebody really wants to find you they can. If you give your call it...

Yes this is true, but you don't have to make it easy for them. They will go
after the easy meat first.

The best bet is not to leave anything the robots can parse and dump into a
searchable database. Then nut cases and spam machines with lots of time on
their hands will use someone else. I learned my lesson 10 years ago from
using my callsign for my screen name and winding up with hundreds of people
from all over the world sending me hate mail because some veeagra and sealis

salesmen were spooffing my address.

If you want an annual index, you type in the year, select the
magazine, set the month to any, and it lists all the articles for that

year.

About locating a feature article... depending on the nature of the article there are keywords like "Construction Project", "Modification", "Homebrew", "QRP", In between title search and keyword search and author search, I've been able to find all the articles that I've been looking for.

Could they improve the searching ability? Oh yeah, sure. I have a freaking hardware-store orgasm every time I go to http://www.mcmaster.com/ just give it a try, I can start typing "Gear Puller" in the search box and even before I finish the word puller, I have the catalog page in front of me with pictures of all the relevant dimensions and types. That's really good! I've used a lot of web-based search utilities and I'd rank the ARRL QST online index/search engine as above average but nowhere near the best.

Hi All,

NXP have just made available their =94RF MANUAL 11th Edition=94

You may download the file visiting:

http://www.nxp.com/acrobat_download/other/discretes/nxp_rf_manual_11th_edit=
ion.pdf

Enjoy the reading and good download

73

The mains rectifier could use some filtering too. Im thinking using
the caps out of some old PC power supplies

Lots of good parts in a PC power supply...

Use the NTC inrush limiter resistors from the old PC supply
too so the caps don't pound the snot out of the on-off switch
and line recifier.

Yeah, I was planning on using pretty much the whole input section to the PC power supply. The one I am looking at I think I can cut out the whole circuit with a coping saw and mount it on some standoffs. This would put the rectifiers and caps on a seperate little chassis and I wont have to shoehorn in the 'lytics on to the inverter board.

I was noticing that the schematic for the 120VAC uwave inverters is pretty much the same as the 240VAC inverter. I was expecting mains input to be different. What I was expecting was a voltage doubler on the 120VAC board since the 240VAC board used a bridge. This would mean that the inverter section is designed to run off of anything from 150VDC to 300VDC . I need to take a closer look at just what are the differences in the 120 and 240 inverters.

Jimmie

Frankenstein style construction. Hopefully you'll be tempted to
shout "IT'S ALIVE!" but without the arcs and sparks.

A 2:1 input range is a piece of cake for a flyback. An 8:1
range isn't unheard of in commodity products. Not being
strictly bounded by the transformer (coupled inductor) turns
ratio can be handy!

There need not be any differences in the power components.
The control parameters important to operation of the oven
might need adjustment though.

That said, optimization for each range could save a few coins.
Make a million ovens or two and it adds up.

I went through the parts list for each power supply and their are some
different part #s for the 120vac
compared to the 240vac unit and the wiring is a little different.

Grumpy, did you want a detailed schematic or did I already give you
one?
Send me an email and I will get one to you.

There are part#s for everything. Maybe you could order just the
transformer if you wanted.

Jimmie

oops, the above was just a test...

Anyway, the FAA and the ARRL both became concerned with stagnation in the late 50's in the Amateur Service and as a result began to thrash about for ways to keep the service growing... Incentive licensing, and all the other changes we see moaned about on this topic were the result of an actual good-intentions series of changes... Those who believe in conspiracy will never understand that, but that is their loss.. The one thing we won't see is the status quo... Change is a constant, even in the stodgy ranks of hams... So no code it is - for now - and even after more than a half century on the bands I do not proclaim to foresee the future, other than be able to announce with perfect certainty, the regs will change... If you do not like the regs now, just wait - you won't...

Now having said that, I am currently working on a series of homebrew pulse desulfators for batteries.. I have one that has been blown up a couple of times, but for the moment is upgraded and again working on knocking the sulfate off the plates of a tractor battery... It has 13.2 volt float with 51 volt pulses at a frequency of ~1kc and ~80ms pulse width... I have delivered and in hand (just yesterday) roughly a $100 worth of parts to build another ten units... I have the design

for generation II of these that will feature boost and burp charging
with ramping of the pulse frequencies...

Next up for gen III will be a 40 volt charger that will be pulse
width and frequency agile that will both charge and desulphate
simultaneously with a far smaller parts count - the square wave
charging pulses doing both actions simultaneously... Today I am
beginning the first tests of the devices that will be able to switch
30+ amps at 40 volts...

denny - k8do

Denny <k8do@mailblocks.com> wrote:

>Incentive licensing,
>and all the other changes we see moaned about on this topic...

My moaning was because of the *unfairness* of the incentive licensing
frequency changes. I passed an examination for General and I expected to be
able to use those General frequencies. Then they took away half the General
frequencies. Even these many years later (even after having regained those
lost frequencies) I think it was an unfair change.

Some may moan that the FCC now gives advanced licenses with no code test and modern hams don't have to work as hard for the license as hams in years past. Which is true. And some may moan that people can now get an advanced ham license by memorization without knowing the advanced electronics pretended in the testing. Which is true. But not me because it takes nothing away from privileges already earned.

I have an idea (analogy). How about we institute an Extra Plus license. Forget the code test because it's obsolete. But to make sure that the applicant is really qualified he must pass a *real* electronics/digital test, one that can't be passed by memorization. No answer sheets. At the FCC office like in the old days.

And....to make the license desirable we take away half of the current Extra privileges and give them to the new Extra Plus.

Whoa, talk about moaning...

Thanks for the schematic Jimmie.

The description of the inverter circuit translated by google says it's both variable frequency pulse and width modulated er... I think. This Could be critical conduction control.

I couldn't find any mention of the flyback topology but my
Portuguese consists of only a dozen or so words that I learned
while living on the east coast and five of those are unseemly.

This Power Supply Reversing receives the 120v or
220v 60Hz AC and provides the entry for the 4000 Vdc
the magnetron tube, before performing the same function
made by the processor and high-capacitor and diode,
high.

. The entry of tension AC120V or 220V 60Hz is retificada
immediately to a voltage DC.

. Voltage DC This will feed a device
IGBT switching required. This device will
chavear On and off for 20 to 40 kHz PWM (Pulse Wide
Modulation) the sign of the microprocessor in the DPC.

. This microprocessor commands the processor high
voltage to amplify and until 2000Vac
3Vac about by the processor.

. Then a circuit of half wave rectifier folder, which
consists of a diode and high voltage capacitors, generate
4000V required for the magnetron.

. The output of the magnetron is always monitored
by the current output of the processor internally
reverse the circuit.

Well, the current extra class license only adds a small slice of extra
phone and cw bandwidth. I lived without the extra class phone segments
for years. Finally got my extra when the cw requirement went away.

The LACK of incentive plus the 20wpm code was the reason so few upgraded

to the extra class, the advanced class license was good enough.
Actually the extra cw segments were the most prized, so the cw
requirement made sense.

As far as techs are concerned... Well I knew quite a few techs who were
very much into home brew radios. Some of the best two meter (and up)
gear I ever saw was home brewed by those guys.
(state of the art in (1970's) mosfet front rx front ends).

Hi all
I have an old FT530 kicking around that I wish to use mobile.
My problem is that I need the pinouts of the jack plugs on the speaker
mic so I can emulate these on the plugs of a hands free / remote TX
switch mic.
I have seen various bits of info for connections but none that states
if I need a DC blocking capacitor or not and what do I connect to earth
to make the radio TX (must this be via a resistor?).
I would appreciate any info on this
please................................

Neil 2E0EJS / M3SGC

I have recently bought a pro-46 scanner on ebay with the hope of doing
some modifications to it. One of the modifications i wanted to do was
to restore the cellular frequency to it. I did tons of searching and
found a few sites that had instructions on how to do it but they were
in text and were kind of vague. I got as far as figuring out which
resistors to remove but the problem is i dont know where to solder it
back onto. I tried a few different locations that i thought were
correct but had no sucess. I dont want to just keep trying different
places in fear of ruining the scanner. If anyone has any knowledge of
this topic and could help i would greatly appreciate it. I can also
provide pictures of the board showing what i have taken off and am
hoping that maybe someone could take the picture and actually show me
exactly where the resistor needs to go. Any help would be appreciated.
Thanks

> to the extra class,

Correct. Before Incentive Licensing there was not much incentive to go above General since there were no additional privileges. Those who did upgrade to Extra did it for the accomplishment.

And since it was a real (no answers supplied) exam before an official FCC examiner it did show accomplishment. Hams of the day often listed it on employment applications alongside their commercial licenses.

>Actually the extra cw segments were the most prized,

Only if you are a CW DXer. And even before the change, by gentlemans agreement the bottom of the CW band was left for DXers and casual CW operation was higher, pretty much like now.

>so the cw requirement made sense

IMO the only justification for the code test (at that time) was for possible emergency use. As an example a ship in distress, since many ships were still using CW at the time. But other than that making a ham take a special code test made about as much sense as making him take a special soldering test. That was finally recognized recently...

>As far as techs are concerned... Well I knew quite a few techs who were
>very much into home brew radios.

As it should be. The Tech license was supposed to be for technical use, not just another operators license. But of course that was a laugh. Most Techs bought their equipment and set up shop on the nearest local repeater...

Hasn't most analog cellular service has been shut down by now? If so your scanner will receive mostly digital hash on the cellular frequencies. Might be wasting your time.

This thing seems to be regulated primarily by the input CURRENT which would be the same as power and David Smith said in his discription. I think the answer to using it as a power supply is to turn it into a VOLTAGE regulated power supply by taking a voltage sample off of the HV transformer, possible by adding a couple of turns coil to the transformer, and replacing the input from the current transformer with this one. Naturally the inpit to IINDO may have to be suitably modified also.

I cant remember now where I saw it refered to as a.flyback circuit but it said "FLYBACK" no trouble with translation.

I will look for it tonight.

Jimmie

Experimenter Techs were the norm IMHO before the debacle of license class changes in the late '70s, and anything related to repeaters before then involved significant accomplishment ;) Please don't lump 'new' Techs with 'original' Techs.

BTW, if anyone knows, I'd appreciate knowing what the grace period after expiration was in 1975 (I was told by a field-office rep that my expired Advanced couldn't be renewed and later I was told that I was probably misinformed and was within a grace period, but I could never confirm that fact).

Michael

I may have met one or two Tech experimenters but the only reason they were Tech experimenters and not General or Extra experimenters was they couldn't get their code speed up. Which is why I always thought that the concept of a Tech being an experimenter type license kind of silly.

Heck there is an electronics whiz named Cecil with a web site all about neat antenna ideas of his. He surely fits the experimenter mold. For eons on these newsgroups he said he wouldn't have an Extra if they gave it to him. Absolutely no need said he. But when the code went away guess what. Yup he's an Extra. So IMO the license class has little to do with being an experimenter...

Not everywhere.

There are still analog sites in remote/rugged terrains where digital is
useless... like northern Alberta.

Cheers!

You can find the manual + circuit diagramme for the FT530   at ;
www.mods.dk   Goto Manuals ---> Yaesu ---> FT530

If you are not (financially)contributing to that site you are allowed to
make 1 download per day (24 hrs)

Good Luck

Frank   GM0CSZ / KN6WH

While brows varios inverter circuits I began to wonder  how difficult
would it be to convert a pulse width modulated power supply into a
power supply /AM modulator. Could this be as simple as appling audio
on the feedback path between the output and the PWM circuit. Just an
idle thought.

Jimmie

You might consider taking a voltage sample by 'tapping' a low DC voltage
fraction from the HV output ,putting that into an opamp with adjustable
output.

You can see how this is done in an article in QEX-July.August 1999
,pages 50-55. 'A regulated 2400 V power supply ' by VE6AXW

Frank GM0CSZ / KN6WH

Is there any more info on the circuit besides the schematic?

This looks like something I could build and I probably already have
most of the parts.

I see it uses SCRs for switching. I guess there is no problem with
latchup. I built a 400Hz inverter one time and it seemed to work for a
while until one day it latched up on me and smoked. I had been using
it to power some selsyn motors. Someone plugged a soldering iron into
the inverter and I think it was a little too much load. I guess that
is what I get for not labeling my outlets.

Jimmie

This whole line is silly because there are all kinds of experimenters in all
license classes (and unlicensed) so how does the fact that I can experiment
on any frequency make any difference.

BTW repeaters are old hat.  Hams were doing remote bases and repeaters in
the 50's.  The biggest changes have been all the available off-the-shelf
equipment since the 70's that spawned the appliance operators that need help
to put up a mag mount antenna.

I thought it was 2 years but it never affected me so I'm not positive. The
upside is you can probably go get a new one with a weeks worth of brush-up.

Ugh! It's very similar to a power supply I worked on in the
mid-1970's for a tacan pulse power calibration system. The
scars had almost healed. There's not much advantage in it
over a vintage blood and thunder supply beyond improved
regulation. No reduction in the amount of steel or output
capacitance needed... lots of stored energy.

Though I did learn a lot about PUT's and SCR's in the process
so overall it was fun. It's also when I learned that power
supply engineers always run Towards the explosion.

Hi Michael,

Yep -- there wasn't a lot of commercial off-the-shelf equipment available (that didn't require any modification) until the mid-late 70s. It was common for a VHFer to modify a Motorola/GE/etc unit to operate on the ham bands.

IIRC, the grace period used to be 1 year but nowadays, it appears to be 2 years w/o having to retake a test:

There was modification of commercial/war surplus gear done by all classes of hams, for all the ham bands, over much of ham history. The Technician (and VHFer) had no lock on modification.

But more important for this discussion, the Technician Class License was defined and supposed to be an 'experimenter' license not a 'modification' license.

And of course most Techs, however they got their gear working, (modification or appliance op), used it as a communicator anyway...

A remote base is different from an unattended repeater.

I dont suppose there is an SMPS pwer supply design book for dummies
ou t there somwhere.
Seriously what would be a good book for transformer design. I
downloaded the info ferroxcube had. I was hoping they had someready
made transformers. I know they have made some for the military/gov,
but I didnt see anything off the shelf available except their cores.

Jimmie.

It isn't unattended if it has a control point.

All I know is that there was one in the late 50's.  I'm not a lawyer or an
FCC spokesman but I suspect the statute of limitations is well past.

```

Still mulling over some RX design changes for a HBR receiver project that I am considering building. It is going to be an updated version of the HBR receiver projects that W6TC, Ted Crosby, penned for QST in the late 50s and early 60s.

I've decided to go with 6EH7 semi-remote pentodes for the RF and IF stages (overload resistant), meaning my filament current requirements are going out of sight.. 4.7 amps so far, so I want to cut back on the number of stages.

To cut my tube count and heater energy, I'm looking for opinions on using 6JH8s with self excited injection. The 2nd mixer requires 1515kc injection, and I'm considering using the 6JH8 as a self-excited crystal oscillator to eliminate using a separate oscillator stage. Original plan was either a 6BH6 oscillator, or 6U8 combined osc/buffer.

Second branstorm is to use a self-excited 6JH8 for the Product Detector and 85kc BFO, eliminating a separate tube and buffer stage that I had originally planned on using (another 6U8). Will osc. pulling be a problem? Any other drawbacks?

First mixer will be a 6ES8 Pullen, with a 6U8 used for the tunable LO and buffer isolation. AGC will be via a 12AU7 plate detector, 12AU7 infinite impedance AM detector, 12AX7 Q-multiplier, 12AU7 first AFA and S-meter amp, and a 6AK6 AFA. First IF is 1600kc using cascaded modified ARC-5 IF transformers. 2nd IF is 85kc, using cascaded R-23 command RX IFTs.

Pete

Howdy,

It's a tough choice, most of the books in the subject have at least a couple of strong points or useful tricks.

If I could have only one book and it had to cover all aspects of SMPS design I'd chose "Switching Power Supply Design" by Abraham L. Pressman.

There are many individual books devoted to topology convolution, wound magnetics design, control systems engineering and the care and feeding of semiconductor switches. So no one book covers evey aspect thoughoughly but Abe's book is pretty good.

He also wrote "Switching And Linear Power Supply Design, power Converter Design", which was his first book. Worth having for sometimes you might need a big linear supply.

"Switchmode Power Supply Handbook" by Keith Billings contains many practical tips.

For magetics "Transformer And Inductor Design Handbook" by Colonel Wm. T. McLyman is good. Another good book is Magnetics Engineering Fundamentals and Computer Aided Design" by Fred M. Lillenstein.

"Transformers for Electronic Circuits" by Nathan Grossner is good too, especially for heavy metal. There is a copy of it online at some tube audio site but I can't find the link off hand.

Also check the free software and app notes at Magnetics Inc. And at Micrometals Inc. too.

Some decent vendors of needed odds and ends are Pleo, lodestone pacific, Robison Ind.,Dexter, MH&W. CWS Coil Winding Services is worth checking out too.

For built transformers you'll mostly find low voltage and telecom stuff off the shelf. Can't recall seeing any high power (more than a couple of hundred watts) high voltage transformers off the shelf. Even low power HV stuff is rare unless you count the measly few hundreds of volts for EL and neon lighting.

I really think this is a roll your own kind of affair. Furukawa
TEX-E triple insulated wire might be handy without a segmented
secondary bobbin.

I hope you find some of this useful. There are a LOT of books on
these subjects. Enough to cause my house to sag under the weight.

My big problem at the moment is designinging a transformer. after much
reading in the last couple of days I am begining to think it is not
the big deal I thought it was. Since I am not trying to build 50k
units I dont have to use the cheapest thing I can get by with and can
overdesign a bit. I can see that just a few cores may take care of all
of my needs. Oh well its back to work so it will be a few days before
i get to piddle with this anymore. One of my jobs this week is to go
through all the old UPSs we have in the store room and find out which
ones are good and chunk the rest.

Jimmie

Here's a history in three parts. It was written in 1999 and so doesn't
cover the 2000 restructuring, but you'll find a lot of background in
there.

Part 1:

http://groups.google.com/group/rec.radio.amateur.policy/msg/5e237c8d619c6a9=
0?hl=3Den&dmode=3Dsource

or:

http://tinyurl.com/6o8bzf

Part 2:

http://groups.google.com/group/rec.radio.amateur.policy/msg/932c3e0a55b5cfd=
a?hl=3Den&dmode=3Dsource

or:

http://tinyurl.com/6lupxx
```

Part 3:

http://groups.google.com/group/rec.radio.amateur.policy/msg/711fd670748942f=
f?hl=3Den&dmode=3Dsource

or:

http://tinyurl.com/6dosbw

A couple of points:

1) "Incentive licensing" came into being in the 1960s
2) It wasn't a new thing, but rather a return to the way things used to be before 1953. Except it was a lot more complicated.
3) ARRL had a big role but wasn't the only one involved. There were at least 10 other proposals given RM numbers by FCC, over 6000 comments at a time before ECFS and the internet, and the result went into effect in 1968.
4) The Tech had a code test until 1991.
5) The ARRL did not want the VE system. FCC pushed it on us to save money.

I built a Class D push-pull CW HF TX with 74HC240s providing oscillation, buffering, an extra inverter on one side, and two stages of current amplification, eventually driving a pair of IRF530 MOSFETs..

It looks like I struck a good balance even if there was a phase offset.

This is what happened.

I turned ann inversting 8-section driver 74HC240 from a single-ended oscillator->buffer->4Xamp (N7KSB style), into this push-pull monster:

```
                          | -inverter-2Xamp-16Xamp-...
VXO-buffer-buffer-|
                          |-------------2Xamp-16Xamp-...
```

From VXO to the 2+2 sections in push-pull current amplifier, all fits into one 74HC240, fed at 5Vdc. Then, in a 8X equivalent fanout, I put 2 x 74HC240 on each side, fed at 8Vdc. 16 sections of current amplification per side provide A LOT of current, already delivered over 1W RF, and proved more than sufficient for driving a pair of IRF530's in push pull with individually trimmed positive DC bias, probably with room for further expansion.

The interesting fact is that there is one extra inverting section on one side only. On that side the signal should have been delayed by 20-30ns, the propagation time for one section. At 10MHz this should equal 70-110 degrees. In theory this should mean that both push-pull sides should spend 110 degrees in high status (MOSFETs conducting), and 110 degrees not conducting, leaving only 140 degrees for honest-to-G_d pushpullery. :-(

Woe betide such a push-pull... BUT... with my scope having one channel KO, I can't juxtapose the events - I can only combine the results in the output transformer.

The result seems like a pretty symmetric waveform, with steep voltage peaks on both sides (output balun primary still not tuned). Once filtered into a sinusoid, I see about 60W DC going in and about 45-50W RF coming out, with negligible second harmonic.

Is this normal? What did I get wrong? (I.e. got right, but just by chance). Would I be wasting my time if I sought more push-pull symmety by means of an unbal transformer? I mean somethign like this:

```
                       |-buffer-2Xamp-...
VXO-buffer-unbal
                       |-buffer-2Xamp-...
```

Any wisdom welcome!

[OK, I am going to have the scope's 2nd channel fixed anyway... :-)]

> From VXO to the 2+2 sections in push-pull current amplifier, all fits into one 74HC240, fed at 5Vdc. Then, in a 8X equivalent fanout, I put 2 x 74HC240 on each side, fed at 8Vdc. 16 sections of current amplification per side provide A LOT of current, already delivered over 1W RF, and proved more than sufficient for driving a pair of IRF530's in push pull with individually trimmed positive DC bias, probably with room for further expansion.
>
> The interesting fact is that there is one extra inverting section on one side only. On that side the signal should have been delayed by 20-30ns, the propagation time for one section. At 10MHz this should equal 70-110 degrees. In theory this should mean that both push-pull sides should spend 110 degrees in high status (MOSFETs conducting), and 110 degrees not conducting, leaving only 140 degrees for honest-to-G_d pushpullery. :-(

Well, if the second harmonic is really low then you must have a good square wave. On the output side you could determine the phase relationships by looking at the symmetry of the square wave. Adjust the phase with an rc network on the input of one of the parallel shortest delay stacks of 74hc's. I have paralled several 74xx series of chips together before and found that the propagation delays were within the spec's but varied a lot within those specs. After you tune your primary you should get a really good sine wave out of the amp. I would not go through the trouble of unbalancing the transformer as this could result in some unusual spikes on the output due to saturation of the core, or cross conduction of the Fets due to di/dvt issues. One other thing comes to mind is that with a torrid core at high current and a high frequency, then symmetry of the winding itself is critical. The spacing of the winding should fill the whole core and be spaced as uniform as you can make them. Having said that, then, match 2 IRF530's for rds on. (A few tenths of an ohm really makes a big difference when you are throwing around a bunch of amps.) This will go a long ways in preventing what looks like an unbalanced output transformer at 10 Mhz.

Sounds like your on the right track. Just a little bit of tweaking to go to get there.

Thanks Rich!

On Sep 17, 4:55=A0pm, "Rich Klestinez" <replytogr...@noplace.cc> wrote:
>> I would not go through the trouble of unbalancing the transformer

I didn't mean to... The idea was to generate two symmetrical and opposed signals by putting an un-bal transformer between the VXO and a first push-pull stage made with just two sections, charged with rebuilding near-square waveforms.

I matched neither driver sections nor MOSFETs,but I did hear that both can be a bit variable. Apparently the chip drivers are normally used without equalization (to the surprise of quite a few authours). As for MOSFETs, I saw several amp designs with a single separate bias trimmer, or with a single special driver chip, for several devices. I have separate trimmers, I didn't bother to check if the 1-mA voltage was the same for both - but I will. That may have helped equalize the switching point in terms of RF voltage. As for the different on-state resistance, I guess it's more critical if one has devices in parallel - in a push-pull a particularly low resistance device won't hog the current.

>> One other thing comes to mind is that with a torrid core at high current=
 and a high frequency, then symmetry of the winding itself is critical.

Yes, I've been extremely careful. Winding is trifilar, twisted, I took care to have symmetrical twist pitch and winding spacing.

>> torrid core

Torrid indeed. Now I have a tiny .82 core and thin wire too. At normal duty cycle all is fine, after 120s keydown one risks minor burns - but the MOSFETs barely get warm.

Coincidentally, I just got several 10s of feet of Raychem "high performance" wire after helping assemble a prototype 4-fuel car (3 liquid fuels + plugin recharger). 1.5sqmm, silver plated stranded copper alloy, thin 600V radiation-crosslinked high temperature insulator. I've been verbally told the 1/2sqmm variety can carry 30A (I asked as I worried it would not bear 3.5). I will try it on a larger core. I already recovered the ferrite of a 1-kW Hi Gain balun, but I want to see detailed wire specs first. Once stripped, this wire should do well in hi-Q coils too.

Here's a history in three parts. It was written in 1999 and so doesn't cover the 2000 restructuring, but you'll find a lot of background in there.

Part 1:

http://groups.google.com/group/rec.radio.amateur.policy/msg/5e237c8d619c6a90?hl=en&dmode=source

or:

http://tinyurl.com/6o8bzf

Part 2:

http://groups.google.com/group/rec.radio.amateur.policy/msg/932c3e0a55b5cfda?hl=en&dmode=source

or:

http://tinyurl.com/6lupxx

Part 3:

http://groups.google.com/group/rec.radio.amateur.policy/msg/711fd670748942ff?hl=en&dmode=source

or:

http://tinyurl.com/6dosbw

A couple of points:

1) "Incentive licensing" came into being in the 1960s
2) It wasn't a new thing, but rather a return to the way things used to be before 1953. Except it was a lot more complicated.
3) ARRL had a big role but wasn't the only one involved. There were at least 10 other proposals given RM numbers by FCC, over 6000 comments at a time before ECFS and the internet, and the result went into effect in 1968.
4) The Tech had a code test until 1991.
5) The ARRL did not want the VE system. FCC pushed it on us to save money.

In 1975 the grace period was 1 year. License terms back then were 5
years.

Actually, the period when Generals-and-above had all privileges was
less than 16 years (Feb 1953 to Nov 1968). Before Feb 1953, you needed
an Advanced or Extra to use 'phone on the ham bands between 2.5 and 25
MHz.

.
> That was finally recognized recently... =A0

There were three reasons for it back then:

The first reason was the ITU treaty, which required Morse Code testing.

The second reason was that the FCC considered Morse Code skill to be part of what it meant to be a qualified radio amateur, particularly one that had full HF privileges. That view has changed since the 1970s but it was a big thing to them in those days.

The third reason was that before the 1980s amateur radio was quite different in terms of equipment and mode/band choices. There were no WARC bands (30, 17 and 12 meters) before 1979, and 160 was full of LORAN and hams only had limited use of it. The only data mode was RTTY, done with big heavy electromechanical teletype machines. SSTV existed but required special equipment. So most hams on HF used either Morse Code, SSB or AM. SSB and AM use a lot more spectrum than Morse Code so the total carrying capacity of the HF ham bands would be much less if everybody used voice.

That depends on what era you're talking about. The Technician was created as part of the 1951 restructuring, and originally did not include 6 or 2 meters. Repeaters did not become common in ham radio until the 1970s.

They took away half of the General *phone* frequencies on 75, 40, 20
and 15 meters. And 25 kHz of the 80, 40, 20 and 15 meter CW/data
frequencies.

I remember the moaning back then. Basically it came down to the idea
that many hams felt they'd earned the right to full privileges forever

by passing the General test, and shouldn't be required to pass any
more tests.

btw, I earned my Advanced in the summer of 1968 and had full
privileges for a few weeks until the rules changed in November 1968.

The problem is that changes in the requirements change the nature of
the ARS. Not right away, but over a long time.

> I have an idea (analogy). How about we institute an Extra Plus license.

Won't happen because FCC won't take on that job again.

From 1951 until about 1953 or 54 the Novice and Tech were given at FCC offices unless you lived beyond a certain distance from an FCC exam point.

But the new licenses made so much work for FCC that they changed the rules and made both those licenses "by mail".

There was also the by-mail equivalent of the General license, called the Conditional. In the mid-1970s it was merged with the General.

I remember that when it was announced that the Conditional was being phased out, there was a false rumor that FCC would require all Conditionals to retest. You should have heard the cries of anguish! I found that puzzling because the tests weren't *that* hard. Now I have a little better understanding...

> I always wondered why if the Tech was an experimenters
> license as the FCC claimed it was, why they required a code
> test.

Because the international treaty required it. Over time that changed, but in the 1950s any license that allowed a ham to use the bands below 1 GHz required a code test.

Not any more. But in the past it was very different.

> > > I think that the ARRL had more to do with the snafu's of that era. Fo=
r
> > > example incentive licensing.

Which was not really an ARRL idea - nor a new one in the 1960s.

 of
> the chronology from memory.
```

>
> The 11 meter ham band was taken away to make the Citizens Band in 58? =A0=
 It
> didn't turn out anything like the FCC expected.

Yup. Actually FCC had created UHF cb where FRS/GMRS is now a decade
earlier, but 1950s technology was such that a good UHF radio was big,
heavy and expensive. So they reallocated 11 meters (which wasn't a ham
band by treaty) because decent sets would be a lot cheaper to make.
FCC never imagined that so many people would just ignore the rules.

>=A0Previously there were fewer
> ham license classes and everyone was on the same page. Also privileges we=
re
> taken away from the highest class to make a higher ones. =A0Ticked off a =
lot
> of Hams to lose.

Before 1951 there were three license classes, A, B and C. The 1951
restructuring renamed them to Advanced, General and Conditional, and
added the Novice, Technician, and Extra. That 1951 restructuring was
not an ARRL idea, btw.

> The Technician License split ham radio into two factions by offering a

> People who took the Novice ticket were upgraded to General in less than 2
> years or never got around to get on the air and let it lapse.

There were always lots of factions. There were the 'phone folks and
the CW bunch, the traffic handlers and the DXers, the homebrewers, kit
builders and factory-made groups, the mobileers, the VHF/UHFers, the
ragchewers, etc. Few of the divisions you see today are new.

Some folks still do. Google my call, for example...

>=A0Techs at that time were expected to retune or modify a rig
> or some project as well but would go straight to CB like intercom operati=
ons
> not conducive to learning the HF skills for upgrade.

I think the real problem was that there wasn't much casual CW
operation on VHF, and many low-cost VHF rigs wouldn't even do CW.

>=A0In my day we were

ch
> other again and again, so no sense carrying a grudge.

Agreed! There were other forces at work, too. For one thing, equipment
was expensive compared to today and you needed to know something just
to tune it up and get on the air. For another, getting a license
required that you invest some time and effort into learning code and
theory.

The FCC was also a respected and almost feared entity before the cb
boom. Hams knew FCC was listening, and would find them if they
misbehaved.

> In the late 70's there was a push by ARRL to get CBers interested, and ov=
er
> the counter 2 meter radios were first becoming available.

I don't recall that at all. ARRL pushed repeaters and FM because they
were new technology, for hams anyway, and were already popular with
hams in some parts of the country.

> ARRL didn't seem to understand that CB was a different service with a

I don't recall that at all.

>=A0 Wayne Green was one of the ticked off ones and
> started 73 magazine to rag about the ARRL and QST.

Wayne Green was a lifelong gadfly. He's still around, btw. Says the
Apollo moon landings were faked, among other things.

>=A0ARRL also convinced the
> FCC (easily) to set up the volunteer examiner program.

Nope, not true. FCC did that in the early 1980s to reduce their
workload. Their funding wasn't keeping up with their costs and they
had to reduce costs somehow. ARRL had no choice.

>=A0Novice exams were
> already given by volunteer Extras.

Actually a General or Advanced could give Novice exams.

>=A0FCC wanted to lighten their work load
> since Ham testing and licensing was taking up most of a day at the field
> offices.

The office in Philly where I took my tests was busy three days a week
with exams.

> License renewals were then made easier and for longer. =A0ARRL liked it

Yup.

> The no-code Tech license 83? further divided amateurs and even further
> sidetracked Techs from upgrading.

1991, not 1983. Don't forget code waivers, created in 1990 as a favor
of then-president Bush to ham who was also a King.

>=A0Lead time for getting a ticket was

There were also folks who got into ham radio back then to use it as a
personal communications
system without all the headaches of cb. Sometimes whole families got

```
licensed and got HTs just to keep in touch. We had a lot of them in
the 80s and 90s. Cell phones killed that.

ept
> track of all the current structure since I got my Extra in 93.

The changes have been a little here and a little there. It was FCC,
not ARRL, who has pushed for reduced requirements since the late
1970s.

> In any case, the "incentive" licensing structure was anything but incenti=
ve.
> So much for good intentions.

Consider this, though:

In 1951 there were about 100,000 US hams.

By 1962 or so that number had grown to about 250,000.

But then the growth slowed to a trickle and by 1969 there were only a
few more than there were in 1962.

Some said the incentive licensing changes would kill off ham radio,
but instead the numbers grew all through the 1970s and 1980s and into
the 1990s. Not just Techs but Generals and above too.

btw, I got my Novice in 1967 (age 13), Advanced in 1968 (age 14) and
Extra in 1970 (age 16). I didn't think any of the tests were very
hard. Would have gotten the Extra sooner but in those days you needed
2 years experience as a General or Advanced just to try the Extra
test.

FWIW, I found some good material on this subject in the
March 1960 QST, pps 33 - 38.

Another question: I've been told that the 6JH8 works best
with 0 volts on the deflector electrodes. However, it was
common practice with the 7360 to use a voltage divider
between the plate and deflector to provide negative feedback
(improved linearity) while biasing and balancing the
deflection electrodes. I'm thinking of using the same scheme
on the 6JH8, except having the low end of the voltage
dividers going to a negative bias source. That would allow
setting the electrode voltages to 0 volts, or slightly negative
or positive--whatever works best--while still keeping the
advantages of having negative feedback from the plate.
Is this worth doing?

Pete

Howdy,

I found the URL for Grossner's book online.
http://tinyurl.com/3z7mxv

It seems to me that using the inverter oven transformer
and IGBT with a flyback controller like UC3842 might work.

Just a straight enough, hard-switched, flyback with single
ended output. You'd "only" get 1.5-2KV out less output power
maybe one half to three quarters as much... but that's not bad.

Mmm! Old UPS's have lots of good parts in them, especially
the ones with big 60Hz transformers and big heatsinks. Chuck
them into the trunk of your automobile.

> My big problem at the moment is designinging a transformer. after much

Even if there was no treaty, the ham employees in the FCC didn't want no-code. The ARRL didn't want no-code. And the average (already) code tested ham didn't want no-code. It's not surprising therefore that as a political body the FCC just agreed with it's constituents.

> I remember the moaning back then. Basically it came down to the idea
> that many hams felt they'd earned the right to full privileges forever...

I think the moaning was over the basic unfairness of *removing* privileges already earned. Over the years there has been many unpopular (to some) license changes but virtually all (maybe all?) involved giving new applicants easier privileges, not taking away already earned privileges.

> btw, I earned my Advanced in the summer of 1968 and had full

Early SSB exciters used the 7360 tube as a mixer / vfo so I know this
type of tube will work as a self excited converter. As far as pulling
is concerned this would depend on the difference between the oscillator
and IF frequencies, or the oscillator and signal frequencies. But
pulling shouldn't be any worse than with the pentode mixers that
couplied the oscillator to the same grid as the signal input. At least
the 7360 isolates the signal and oscillator to different electrodes.
Also the signal input is balanced and shielded by the screen grid.
OTHO I don't know how good (stable) an oscillator this tube is.
Probably better as a crystal oscillator than a vfo.

Nor did the non-ham employees, until the mid 1970s.

And there *was* a treaty that FCC wouldn't ignore.

> The ARRL didn't want no-code.

If you mean the membership didn't want it, you're right.
> And the average (already) code tested

l
> body the FCC just agreed with it's constituents.

Because the constituents made themselves heard.

Yet as early as 1975 the FCC was trying to create a nocodetest ham
license. The opposition was clear and they backed down. FCC tried
again in 1983 and the opposition made them back down. But in 1991 FCC
did it anyway.

> >I remember the moaning back then. Basically it came down to the idea
> >that many hams felt they'd earned the right to full privileges forever..=

>
> I think the moaning was over the basic unfairness of *removing* privilege=
s
> already earned.

That's what I said - many hams felt they'd earned the privileges
forever, no matter how much things changed.

IMHO one of the driving forces was Sputnik and its cousins.

Up until October 1957, the USA had been confident that we were way
ahead of the Soviets in technology. We had jet planes, they were still
using props. We had transistors, computers, color TV, they were way
behind. Etc.

Then Sputnik went up, and the USSR got a first in the history books. It was soon followed by a bunch of other firsts - first animal in space, first pictures of the far side of the moon, first interplanetary probe, and then the first human in space. It was a shock that had repercussions in a lot of ways, one of which was more emphasis on math and science in schools. Another was raising the expectations of ham operators.

Of course it took time to change the rules.

> Over the years there has been many unpopular (to some) license changes but virtually all (maybe all?) involved giving new applicants easier privileges, not taking away already earned privileges.

Since 1969 that's been the case, because nobody wants to be blamed for "incentive licensing version 2".

> >btw, I earned my Advanced in the summer of 1968 and had full privileges for a few weeks until the rules changed in November 1968.
>
> And you didn't moan at all??

Nope. I just went and got an Extra the first time it was legal for me to try for it. Summer 1970.

> Give me a break...

I won't lie to you and say I complained when I didn't. I was a new ham in 1968 and I knew the rules were going to change, so I just upgraded. It was a challenge, not something to complain about. Haven't regretted it since.

I think what bothered a lot of hams back then was that they'd let themselves get really rusty on both code and theory, and the thought of having to pass more tests was really daunting. On top of that, the Advanced and Extra tests couldn't normally be done "by mail" like the Novice, Tech and Conditional, so they'd have to face The Man From FCC rather than another ham for the exams.

All ancient history now. The VE system has been in place for a quarter of a century, Generals now have at least as much 'phone space as they had in 1968, and we're effectively down to three license classes (almost).

The very /best/ mixer I ever made used the 7360.

I tried several other types of valve ("tube" - U.S.) mixer, but /nothing/ came even slightly close. The isolation of the local oscillator from the incoming signal, the conversion gain, the accuracy of balance and the bomb-proof nature of the mixer made it superior to /anything/ else I've ever tried. In my receiver, there's a font-end amplifier, using a variable-mu pentode then the 7360. It handles a bigger dynamic range than /any/ other mixer.

The VFO is a "Kallitron" type, using two FETs and a PIC-based huff-and-puff stabiliser (in 10 Hz steps) and two bipolar buffer amplifiers to drive the grids of the 7360. The PIC also drives an LCD display of frequency, and frequency stability is spectacular.

I can assure you - /there/ /is/ /no/ /substitute/ for the 7360. Simply don't consider /anything/ else. Professionally, I've worked extensively on "H-mode" switched mixers - often using very advanced components - and can tell you that the 7360 out-performs /everything/ else!

One other thing - self-excited mixers /never/ perform well. You should
re-think your approach.

AJ Lake wrote:

> I predict it will be only one license eventually.

It (effectively) is over here in the UK. We do have a limited "novice" licence, but there's little point in going for that. Most people just go for the full licence.

We used to have "A" and "B" licences - the "A" was all bands, all modes, and the "B" was limited to above 50 MHz and didn't require the Morse Test. The requirement for the Morse was removed, so now it's all amalgamated into one licence.

C.

Was there much moaning over there over the loss of the code test?

In any of your license changes have practicing hams ever lost frequency privileges they had previously earned?

Had there not been a treaty requirement, FCC might have not had a
Morse test for Tech from the beginning. We'll never know.

>I never used CW as a Tech. Heck I was too busy working 6M DX
> (on AM) during that best of all cycles during the late 50s. But I suppose

A lot of VHF/UHF experimenting in those days did use Morse Code and
still does today. EME (moonbounce), meteor scatter, aurora,
troposcatter and other "weak signal" work was almost all CW. Most of
it still is. Of course those were specialized things back then.

> >Then Sputnik went up, and the USSR got a first in the history books.
>
> Yes, remember it well. I listened to Sputnik on my S40.

Then you may remember the reactions. All of a sudden we were #2 and
that wasn't good enough.

> >It [Russian technology] was a shock that had repercussions in a lot of w=
ays,
>
> Yup. Got me many years of employment (government contracts).

And convinced FCC to be dissatisfied.

> >nobody wants to be blamed for "incentive licensing version 2"
>
> Can't blame em. One screw up was enough.

Was it really a screw up? I think the real mistake was back in 1952.

What happened was that in 1951 the FCC restructured the ham radio
license classes and added a whole bunch of new license classes. That
restructuring was in part due to proposals from two small groups
(membership a couple of thousand each) who argued that the then-
current US amateur license requirements, even for Class A, were too
easy.

In those days it took an Advanced (old Class A) for full privileges.
Which meant taking another 50 question written test for hams with

Generals. The new Extra also had full privileges but had more requirements like 20 wpm code, a 100 question written, and 2 years experience.

But as part of the 1951 restructuring, FCC announced that at the end of 1952 they'd stop issuing new Advanceds. So if a ham didn't have an Advanced by the end of 1952, s/he'd have to go for the much more involved Extra.

A considerable number of hams rushed to get the Advanced before the door closed at the end of 1952. But then, in a surprising about-face, in mid-December the FCC announced that as of Feb 1953 all Generals, Conditionals, Advanceds and Extras would have full operating privileges.

You can just imagine the reaction from hams who'd worked hard to get their Advanceds or Extras, then suddenly found the HF 'phone bands flooded with Generals and Conditionals who had the same privileges.

I don't know why the FCC suddenly reversed their plan, which they'd taken several years to develop. Or why they didn't just leave things the way they were in 1952, and left the Advanced open to new issues.

Nobody I have talked to, nor any reference I have read, gives any reason for that Great Giveaway. And most of the hams licensed after 1952 that I have encountered have no idea of that piece of history.

When I first got interested in getting a ham license I bought the ARRL License Manual for fifty cents. I clearly remember opening it up and seeing the chart of license classes and privileges. I thought that it was incredibly odd that there were six license classes, but four of them (General, Conditional, Advanced and Extra) all carried exactly the same operating privileges. What was up with that? I thought then (and still do) that it made no sense at all.

> >Generals now have at least as much 'phone space as they
> >had in 1968,

> I could have just kept my old General (or even Tech) license. That's all =
I
> really need these days for CW ragchewing.

The circle is complete.

I remember in the 1960s thinking that the incentive license idea was good but the application was bad. I thought what should have been done was to increase the privileges of Advanceds and Extras rather than taking anything away.

For example, in those days on 80/75 the Novice subband was 3700 to 3750 and the 'phone subband was 3800 to 4000. 3750 to 3800 was where the foreign 'phone stations hung out to get away from US QRM. Why not make 3750 to 3800 a phone band for Extras only? And make 3775 to 3800 a phone band for Extras and Advanceds? Similar things could be done to other bands.

Another incentive would be increased power. The old rule was 1000 watts input; I thought a lot of hams would have upgraded if Extras were allowed, say, 2500 watts input. Sure it's only a couple of dB but that never stopped anybody.

I also thought that optional distinctive callsigns for various license classes would be a good incentive too. (That one actually happened, but it was many years later).

> >and we're effectively down to three license classes (almost).
>
> I predict it will be only one license eventually.

Maybe, but it will take a very long time. In seven years we've lost only about 1/3 of the Advanceds. And the FCC doesn't seem inclined to give automatic upgrades nor to merge license classes except by renewal.

I've come across Advanceds who say they like their license because it supposedly proves they passed 13 wpm code. But in fact it doesn't, because from 1990 to 2000 one could get any class of license with 5 wpm and a medical waiver.

The first license class to disappear completely will be the Tech Plus, because FCC has been renewing them as Technician since April 2000. In another 19 months the last Tech Plus should disappear.

The Novice license totals are now well under 20,000 (from 50,000 in 2000) and is also dwindling.

Who will be the very last Novice? The very last Advanced? How long will it take for those license classes to disappear?

There are occasional changes, but they are mostly in our favour (like when
we got 50 and 70 MHz bands, previously used for VHF TV).

I was reading up on push-pull topology of switching power supplies
and see that they have problems with flux imbalance. I used to work on
some power supplies that were push pull when I was in the USAF and the
driver transistors were always failing, now I know why. I see that
this isnt as much of a problem for FETs, How about IGBTs.

Jimmie

>early 60s.

Interesting! But be aware that the W6TC design has its flaws.

The first is that there are a lot of stages before you get to the selectivity, which limits the dynamic range. The second is that the tunable LO operates at a high frequency on the upper bands and uses plug-in coils, which limits the thermal and mechanical stability as well as having different calibration on each band.

>I've decided to go with 6EH7 semi-remote pentodes for the RF and IF stages
>(overload resistant), meaning my filament current requirements are going out
>of sight.

6EH7 is a good tube. The receiver part of my rig (google my call) uses one in the RF stage and one in the first IF, with a 7360 mixer.

Some must-read QST articles are:

W1DX's article about "what's wrong with our present receivers", January, 1957

The Squires-Sanders article about using the 7360 as a receiver front-end mixer, September 1963

The "Miser's Dream" rx with 7360 mixer and other neat ideas, by W1DX, May 1965

W1KLK's "Experimental Receiver for 75 meter DX", February 1972

An article about the 7360 product detector for the HBR, December 1960

A 6 meter SSB transmitter using the 6JH8 as a high-level balanced modulator, October 1963

The RSGB Handbooks of the 1960s are the best for receiver ideas using the 7360, IMHO.

I know of one design using the 6JH8 or its cousins the 6ME8 and 6HW8. (The 6AR8 is an early tube that is reportedly microphonic).:

http://g4oep.atspace.com/retro/retro.htm

Worth a look!

> 4.7 amps so far, so I want to cut back on the number of stages.

One word: Don't. Use a bigger power transformer, or an auxiliary heater transformer instead. The rx you describe is a big project, why compromise it? With a separate heater transformer having its own power switch, you could put the critical oscillator heaters on it and let them run semi-continuously.

>To cut my tube count and heater energy, I'm looking for opinions on
using
>6JH8s with self excited injection. The 2nd mixer requires 1515kc injection,

>and I'm considering using the 6JH8 as a self-excited crystal oscillator to
>eliminate using a separate oscillator stage. Original plan was either a 6BH6
>oscillator, or 6U8 combined osc/buffer.

The 6BH6 draws only 0.15 A of heater current. IMHO that small saving is not worth the compromise.

Self-exciting the 6JH8 means the signal will go into the deflectors rather than the grid. That's the opposite of usual receiver-mixer practice, where the oscillator feeds the deflectors. I don't know what the noise figure will be, but I do know that all the beam-deflection receiver mixers I've seen put the signal into the grid for high gain and low noise.

The only places I've seen the signal on the deflectors and the oscillator on the grid is in high-signal-level applications like transmitting balanced modulators and mixers, and receiving product detectors, where noise figure isn't really an issue and low gain is OK.

>Second branstorm is to use a self-excited 6JH8 for the Product Detector and
>85kc BFO, eliminating a separate tube and buffer stage that I had originally
>planned on using (another 6U8). Will osc. pulling be a problem? Any other
>drawbacks?

I don't know if you really need a buffer stage on the BFO. A 6BH6 will do the job. See above about where the signal goes.

>First mixer will be a 6ES8 Pullen, with a 6U8 used for the tunable LO and
>buffer isolation.

How stable an oscillator is acceptable?

> AGC will be via a 12AU7 plate detector, 12AU7 infinite
>impedance AM detector, 12AX7 Q-multiplier, 12AU7 first AFA and S-meter amp,
>and a 6AK6 AFA. First IF is 1600kc using cascaded modified ARC-5 IF
>transformers. 2nd IF is 85kc, using cascaded R-23 command RX IFTs.
>FWIW, I found some good material on this subject in the
>March 1960 QST, pps 33 - 38.

Straight out of the RCA Transmitting Tube manual. (RCA considered the 7360 to be a transmitting tube!)

>Another question: I've been told that the 6JH8 works best
>with 0 volts on the deflector electrodes. However, it was
>common practice with the 7360 to use a voltage divider
>between the plate and deflector to provide negative feedback
>(improved linearity) while biasing and balancing the
>deflection electrodes.

I'm not sure about the negative-feedback part but I do know the idea was balance. And the 7360 deflectors were supposed to be biased a couple dozen volts positive.

>I'm thinking of using the same scheme
>on the 6JH8, except having the low end of the voltage
>dividers going to a negative bias source. That would allow
>setting the electrode voltages to 0 volts, or slightly negative
>or positive--whatever works best--while still keeping the

>Is this worth doing?

Only way to know for sure is to try. See the G4OEP rx page.

I was seriously considering adding a half-lattice crystal filter at the
first IF; the IF filter in the Heath HR-10 would be do the job. Now,

to find a junker! I'll probably end up cascading
IF transformers at 1600kc to improve the shape factor and hopefully
improve the dynamic range numbers for signals further out on the
filter slopes. I have the transformers, so I might as well use them
in this lifetime.

The second is that the
> tunable LO operates at a high frequency on the upper bands and uses
> plug-in coils, which limits the thermal and mechanical stability as
> well as having different calibration on each band.

But each LO coil is hand calibrated for thermal drift :) I'd think the
Q would be much better using full-sized plug-in coils vs. phenolic
bandswitches and a compromised inductors. Ted's design ran the
LO on low side injection and used second harmonic injection for
the first mixer on the upper bands. That really sucks and kills the
idea of balanced beam tube in the first mixer. I agree, the design
is dated, and the advent of cheap IF filters killed the design. The
harmonic mixing scheme really bothers me.

> 6EH7 is a good tube. The receiver part of my rig (google my call) uses
> one in the RF stage and one in the first IF, with a 7360 mixer.

Check SSB Exciter Circuits Using a New Beam Deflection Tube,
by K2FF in the March 1960 QST. It is one of the better presentations
that appeared in QST. He also shows a self-excited product detector
circuit as one example. I'd think the advantage in the PD with
G1 injection might be improved BFO blowby rejection,
which could otherwise affect the AGC system?
>
>
> I don't know if you really need a buffer stage on the BFO. A 6BH6 will
> do the job. See above about where the signal goes.

The buffer could be used for a CF or phase inverter, if I wanted to
use BFO injection on both deflectors. I know only one needs to be
driven in practice.
>
>>First mixer will be a 6ES8 Pullen, with a 6U8 used for the tunable LO and
>>buffer isolation.
>
> How stable an oscillator is acceptable?

Buffer stage is recommended practice with the Pullen Mixer. It's easier
to use the pentode/triode, and ending not needing to use the stage, than
to add it later..
>
  > I'm not sure about the negative-feedback part but I do know the idea

> couple dozen volts positive.

The negative feedback is mentioned in the QST article; it applies to
the product detector circuit where the deflector bias is taken directly from
the plates of the tube.

The treaty applied to 30MHz and below. Techs couldn't go there. The treaty wouldn't apply to them.

>A lot of VHF/UHF experimenting in those days did use Morse Code

Techs only had 220 and up. Why require a 5 WPM test for moon bounce??

>and still does today. EME (moonbounce), meteor scatter, aurora,
>troposcatter and other "weak signal" work was almost all CW.

If Techs do all that CW work today *without* a code test, what justification is there for requiring the code test back then?

>Was it [incentive licensing] really a screw up?
>I think the real mistake was back in 1952.

My old boss used to moan bitterly about the 52 license change when I worked for him in the 50s. He had been a Class A. But the difference is that in that change he *didn't lose* any privileges. He did lose privileges with the later Incentive Licensing change though. Which change do you think he felt worse about?

>You can just imagine the reaction from hams who'd worked hard to get
>their Advanceds or Extras, then suddenly found the HF 'phone bands
>flooded with Generals and Conditionals who had the same privileges.

Probably like having the HF frequencies flooded by no-coders... 8-O

>Another incentive would be increased power.

If I were made boss, the maximum power allowed for any class would be 100W. And if used as an incentive, start at say 25 W for the entry license. Just think of the reduction in neighbor complaints. Just think of the increase in operator skill...

>Who will be the very last Novice? The very last Advanced? How long
>will it take for those license classes to disappear?

They will likely disappear when they change to one license...
(Like the Class A disappeared.)

Mamas don't let your babies grow up to be radio techs.

I did the Advanced Ham ticket, then 2nd phone when I was 17 and got sucked into MNSO immediately.

Nobody cares about the FCC tickets but the Gov't. The private industry actually holds it against you because you have rules and they don't.
And I'm worn out from always being threatened by people with guns and billy clubs who's first instinct is to smash something if it seems uncooperative.
Then there's the hams "bless their hearts" who put me out of business by doing free work. Retirement is sweet but I'm dirt poor.

That is why I did not go into the radio business.  Friend told me of a job
opening.  I was making about $ 2 an hour more at the time and had a good
retirement package.
The job I was doing did not require any special license or anything.
Working for a large company as an electrician/instrument technician.
Did not have to have an electrical license as large companies don't require
it and neither does the government.

I got my FCC 1st in high school after working tobacco for one
summer. The remainder of my summer vacations were spent
tending AM/FM/TV transmitter sites as summer replacement.
Paid was good for a kid, and I didn't get dirty :)  One of my first
interim "career" jobs was a field tech for RCA/Univac mainframe
systems.  I'm not sure which career (broadcasting or mainframe
```

computer) careers faded into oblivion first. Both are rght up
there with coal delivery techicians and icemen.

Need an AMI S3529 switched-capacitor HP filter. The S3529
and the S3528 LP counterpart were featured in an April '86 QST article
entitled SuperSCAF and Son. I still have the S3528, but seem to have
misplaced the S3529.

TIA,

Barry Newberger

Damn! I just got my degree in coal delivery. I guess I always am a day
late and a dollar short! ;) Guess I'll have to keep my day job (radio
tech...VHF up through 7 GHz)

I have found some better schematics on the inverter. It looks like
modifying the power supply for amateur QRO is very plausable. Where
could I post them so anyone who wanted them would have access?

Jimme

Hams are radio AMATEURS so it is logical that they do work for free,
since they are involved in a hobby.

That's why they have to learn to seperate their hobby from the pecuniary interests of others. So they don't become a target for commercial interests.

If some one or group should be buying or renting radios or systems because their entity has regular need for radio dispatch or communications of a non-hobby nature, they should seek professional help while it exists rather than exploiting the ham.

Of course if we all join the Communist Party and the government volunteers to provide us with free food, housing, clothing, medical and other basic subsistence needs, we should do whatever they want after we finish our compulsory rice picking for the day.

It was the same in broadcasting.  There was always a person
willing to DJ for free, just for the fun of it, at the smaller
stations. Folks who were trying to make a meager living
behind the mikes were at the mercy of hobbyists.
```

You don't see any newbies on here making any rock controlled hets..

```
It's like vinyl records or CD's
they is all gone. They don't want you to know about crystals there is
to much
power in that knowledge. They want everyone dumbed down so they can be
controlled,
that's why they did away with code, nobody will ever know it ever
existed in 5 years time.

Do you have windows movie maker you could put it on youtube.com if
there in some
pix file extension like jgp or gif. I had a single pix that I put in
movie maker with intro caption.
Then downloaded it to youtube. A 15 sec single frame video with intro
caption.

Thanks for bringing it up, that jarred my grey matter. I can post a
video to you tube
Now to figure out how to get that power supply to copy on my scanner.

Once source of crystals is eBay. Another is AF4K (google his call), he
has quite a stock in various holders.

But be prepared to pay more than a few dollars per crystal!

Actually, when you adjust for inflation, crystals cost about as much
now as they did 30-40 years ago. Three dollars back in 1965 is the
equivalent of about twenty dollars today.

You can also do things like use harmonics and overtones of the
crystals to get the higher frequencies.

--

But before you start building, I suggest you reconsider that mixing
scheme.

As I understand it, the receiver will consist of a tunable section
that covers 3 to 3.5 MHz, and a converter section which converts the
various ham bands to that tuning range.

So for 160, you would take the 2 to 1.5 MHz range, subtract it from 5
MHz, and get 3 to 3.5 MHz

For 80, you would take the 4 to 3.5 MHz range, subtract it from 7
MHz, and get 3 to 3.5 MHz

For 40, you would take the 7.5 to 7 MHz range, subtract it from 10.5
MHz, and get 3 to 3.5 MHz

For 30, you would take the 10.5 to 10.0 MHz range, subtract it from
13.5 MHz, and get 3 to 3.5 MHz

For 20, you would take the 14.5 to 14 MHz range, subtract it from 17.5
MHz, and get 3 to 3.5 MHz

For 17, you would take the 18.5 to 18 MHz range, subtract it from 21.5
MHz, and get 3 to 3.5 MHz

I guess you don't plan on 15, 12 or 10 meters.

The main problem I see with this design is on 80 meters. On that band, the tunable frequency is too close to the band being covered, and you'll likely have troubles with feedthrough. For example, when you are trying to listen to a signal on, say, 3.6 MHz, the tunable section will be on 3.4 MHz, and the front-end selectivity probably won't be able to stop strong signals from leaking through.

I suggest you look at other heterodyne schemes, because 80 meter operation will be compromised using the scheme you describe.

Here's one to consider, from G2DAF:

Tunable range is 5 to 5.5 MHz

For 160, you would take the 2 to 1.5 MHz range, subtract it from 7 MHz, and get 5 to 5.5 MHz

For 80, you would take the 4 to 3.5 MHz range, subtract it from 9 MHz, and get 5 to 5.5 MHz

For 40, you would take the 7.5 to 7 MHz range, subtract it from 12.5 MHz, and get 5 to 5.5 MHz

For 30, you would take the 10.5 to 10.0 MHz range, subtract it from 15.5 MHz, and get 5 to 5.5 MHz

For 20, you would take the 14 to 14.5 MHz range, subtract 9 MHz from it, and get 5 to 5.5 MHz (Note that the 9 MHz xtal works on two bands)

For 17, you would take the 18 to 18.5 MHz range, subtract 13 MHz from it, and get 5 to 5.5 MHz

For 15, you would take the 21 to 21.5 MHz range, subtract 16 MHz from it, and get 5 to 5.5 MHz

For 12, you would take the 24.5 to 25 MHz range, subtract 19.5 MHz from it, and get 5 to 5.5 MHz

So you cover 8 ranges below 25 MHz with 7 xtals

Ten meters is left as an exercise for the reader.

For the higher frequencies, harmonics of the can be used. For example, an 8 MHz xtal could be used for 15 meters by doubling.

Here's another one:

Tunable range is 3.5 to 4.1 MHz

For 160, you would take the 2 to 1.4 MHz range, subtract it from 5.5 MHz, and get 3.5 to 4.1 MHz

For 80, the conversion section is bypassed and you use the basic tuning range

For 40, you would take the 7.5 to 6.9 MHz range, subtract it from 11 MHz, and get 3.5 to 4.1 MHz (Note that the second harmonic of the 5.5 MHz xtal used for 160 is 11 MHz)

For 30, you would take the 10.6 to 10.0 MHz range, subtract it from 14.1 MHz, and get 3.5 to 4.1 MHz

For 20, you would take the 14 to 14.6 MHz range, subtract 10.5 MHz from it, and get 3.5 to 4.1 MHz

For 17, you would take the 17.6 to 18.2 MHz range, subtract 14.1 MHz from it, and get 3.5 to 4.1 MHz (Note that the same xtal that gives you 30 meters also works on 17 meters)

For 15, you would take the 21 to 21.6 MHz range, subtract 17.5 MHz from it, and get 3.5 to 4.1 MHz

For 12, you would take the 24.5 to 25.1 MHz range, subtract 21 MHz from it, and get 3.5 to 4.1 MHz (Note that the second harmonic of the 10.5 MHz xtal used for 20 is 21 MHz)

So you cover cover 8 ranges below 25.1 MHz with 6 xtals. If you use harmonics of certain xtals, those 8 ranges can be covered with just 4 xtals.

Ten meters is left as an exercise for the reader.

There are lots of other schemes.

```

The real reason for the popularity of synthesizers is cost. When you need a new rock for every band they get costly, but a synthesizer doesn't. This wasn't practical until chips that could do most of the work became cheap.

The main reason for eliminating the commercial operator licenses was cost too. Here's what happened:

There was a time, not so long ago, when there were a large number of tasks that could only be performed (legally, anyway) by a person with an FCC Commercial Operator license. No others need apply, regardless of experience, education or background. Either you were a Radio Operator of a certain class, or you weren't.

Those licenses meant that a person with a high-school education and some smarts could have a good middle-class income if they had the license. Not that all the jobs were easy, or that you didn't need a certain amount of knowledge to do them, but that the Commercial license became the equivalent of a union card, and the jobs were, in a way, protected by FCC regulations.

In other words, the Commercial licenses protected a craft known as Radio Operators, with a set of skills and knowledge specific to them, and jobs only they could do.

The masters of industry didn't like that, so they prevailed on the FCC to reduce the requirements and eliminate most of the licenses and the requirements for tasks to be done only by Radio Operators. The jobs went with them.

This is also why the maritime services went to satellite-based comms rather than HF and MF radio and Morse Code - it eliminated the need for ships to carry licensed Radio Operators.

Oddly enough, FCC still issues Commercial RadioTelegraph licenses, both First and Second Class, though I don't know where in the USA you can get the required experience for a First Class.

They didn't do away with Morse Code. They did away with the test for it. It was done a little at a time over the past 30 years.

My personal theory on why it was eliminated is this:

Since the early 1980s, the FCC has been required to do more and more stuff with less and less resources. So they have constantly sought out ways to reduce their workload, particularly for radio services that don't bring in $$, like ham radio.

That's why they turned over the job of amateur license testing to the QPC and VECs back in 1983 or so. Instead of paid FCC employees making up and conducting amateur license tests, unpaid volunteers do almost all the work. It's also why they doubled the license term to 10 years about that same time - reduces the number of renewals by half.

Reducing the number of license classes reduces the number of tests and the number of upgrade applications to process. In the old days when there were six license classes, a ham who went from Novice or Tech to Extra could upgrade as many as four times. Now there are only two steps.

Eliminating the Morse Code test means one less license test. Less work.

But even though the last remnants of the Morse Code test were removed back in February 2007, there are still plenty of hams using it on the air. This past Field Day, for example, the group I went with had one Morse Code station and three voice stations, all similarly equipped. There were three Morse Code operators and far more voice ops, yet the Morse Code station made more QSOs than all the voice stations combined. This wasn't a surprise, either.

I guess you downloaded David Smiths diagram. Mine has much more
detail.
Give me an email address and I will get it to you. David Smiths
address in the article is good and he wants a dialog with anyone
interested in this project.
I think the 3 of us need to get together and compare notes and draw in
as many other people into this project as we can. I have about given
up on finding another microwave at the thrift store that uses an
inverter. I guess I will just bite the bulllet and buy one. I have a
few experiments I want to do.

Jimmie

Please email me at 'msg _at_ cybertheque _dot_ org; I'd be happy
to put any data you have into a web page.  I have been pondering
building a HV SMPS for years based on PC PSU parts and have
been following threads in this N.G. on the oven PSU with interest.

Michael

URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

hey jim:
Sorry I wasn't talking Morse code, .
Real Morse code nobody knows. That is lost already gone kaput history.
Vail invented the code you so aptly call Morse, So it's not real Morse
code
it's Vail code. What is really lost: everybody still calls it Morse
code.

I think I could make some money fire up the ole solar powered kiln and
start growing quartz.
I break out that old ARRL handbook that tells you exactly how to cut
the crystals
for the desired frequencies and sell them for 50 cent apiece.
I'd make so much money in volume sales.

Its in the mail.
I think if you had transformer from a microwave oven that a circuit
based on a PC power supply would be doable.
The panasonic uwave uses IGBTs instead of FETS or bipolars the way the
PC power supplies do. I think the use of IGBTs is a good idea given
the voltages and currents.
The uwave inverte also operates at 30Khz with the PC operates at about
12Khz.

What you ain't got no IF?
All those fine numbers and no IF
You know what the image frequency is with no IF?

I think he can get's 12 and 15 meters.
21.5+3.39=3D24.89 the bottom of the 12 meter band.
21.5+3.49=3D24.99 the top of the 12 meter band
17.5+3.5=3D21.0 the bottom of 15 meters for an extra
squeeze the tuning range to 3.95 and
17.5+3,95 =3D21.45 the top of the 15 meter band.

Back in the day the reason for Heterodyne was simple
to get a lower frequency at which you could amplify the signal
more readily getting you more SN ratio and selectivity.

Nobody has ground their crystals from scratch since about the 1930's,
if even then.  I've been licensed since 1972 and in all the time since
then I've never seen anything about it, not in magazines and books
going back to the late 1940's and not in more recent material.  I do
recall the 1964 article in QST about a buy in SOuth America who made
his own tubes.

Go back far enough, and hams just needed crystals within the band.
They had relatively little need for exact frequencies.

I suspect even if the Handbook did give such details at one time,
little bits may be lost since when something is current, "everyone
knows" things that may not be obvious to someone who comes later.

Now, they need them on exact frequencies, and they want them in
nice small packages, none of those FT-243 ones that were held together
with pressure.
```

Even if you can so easily grind a piece of quartz to frequency, packaging
them will be problematic, since a sealed metal case is going to be a lot
more trouble than an FT-243 package.

And Novice regulations required the use of Xtal control, a ready
market...

I suspect even if the Handbook did give such details at one time, little bits may be lost since when something is current, "everyone knows" things that may not be obvious to someone who comes later.

Tools, techiques, sources for raw or processed materials. WWII end provided what seemed to be an endless supply of radio related parts and equipment. Tons of FT-243 xtals, ready to use or to regrind, etc. I remember when one could find surplus 455kc xtals to make SSB filters; they are unobtanium now.

I'm fairly sure is a zero voltage switching converter with active voltage clamp. The series inductor and the 4uF capacitor form a harmonic filter. The resonant switching circuit is the capacitor in series with the upper switch, the primary inductance of the transformer and the capacitor in parallel with the transformer.

So it can be devolved into a single switch feed forward converter function from the lower switch and resonant energy recovery by the upper switch... which results in a quasi push-pull output.

Search patents by E. Miyata in USPTO for more details.

Considering it's purpose, I'd expect this design's output power
is probably in the neighborhood of 750W. Don't confuse this with
the name plate rating. Of course the designer didn't consider
ICAS service so YMMV.

There were articles in QST in the 1920s about cutting and grinding
your own crystals from the raw quartz, making holders, etc. A lot of
work and specialized equipment. The market was such that the
specialists quickly took over in the early 1930s.

After WW2 the enormous amount of surplus dominated the amateur market
for decades. Many of the "new" FT-243 crystals we bought were actually
surplus holders with new crystal inside.

>=EF=BF=BDI do
> recall the 1964 article in QST about a buy in SOuth America who

There's a guy in France doing it today. Has a movie on his website.
But again, lots of work and specialized equipment.

> Go back far enough, and hams just needed crystals within

Well, yes and no.

Some xtal frequencies were more prized than others, because the
harmonics fell in higher bands.

> I suspect even if the Handbook did give such details at one time,
> little bits may be lost since when something is current, "everyone

That's true of many things. Reading older radio books and magazines
can require knowledge of a lot of the jargon and methods of the day.
>
> Now, they need them on exact frequencies, and they want them in
> nice small packages, none of those FT-243 ones that were held
> together with pressure.

The big difference is plated electrodes vs. pressure electrodes.
FT-243s are capable of quite good accuracy; .005% was common, which
works out to 200 Hz at 4 MHz.

Pre-WW2 xtals were big and rugged, but used a lot of quartz. Radio-grade natural quartz came almost exclusively from Brazil, and the
difficulty of supply caused US xtal makers to develop xtal designs

that used less quartz. The FT-243 was ultra-miniature in its time!

> Search patents by E. Miyata in USPTO for more details.

I had a nagging feeling that I'd disremembered the circuit
Miyata developed and tried to look it up. Must be an IEEE
paper since there's no patent in his name that I can find.

But these patents may help: 6936803 and 6884977

This paper seems to describe a circuit close to that oven converter.

It would be interesting to know the phasing of the transformer windings.

Since it's voltage fed and there is no output inductor I would have guessed it was a ZVS flyback supply with active recovery of the leakage inductance energy. A flyback is a constant power output topology by nature, so it's a natural for powering a magnetron. But the waveform in the pdf concering the oven looks like a forward converter. Maybe it's the result of the active clamp?

I've designed flyback converters with outputs of a couple KW for TWT tubes but they were hard switched with multiple rectified outputs on the transformer stacked series to reduce the voltage stress. At low output voltages a flyback is unsuitable for much power because of the high peak current developed in the rectifiers and switches.

Sorry to babble on about this but I found the oven circuit fascinating. The white goods guys are very clever.

I hope you can get it working as a power supply for your amplifier.

Absolutely jim

Looky at the January 1934 issue of QST.it's all there.
A yl friend of mine told me bigger is better, I know she's right
even when it comes to crystals.

As far as accuracy goes you know you can pull it to the frequency you
want
if your'e close enough, it's the oven you need to keep em on
frequency.

I have my doubts about using it as is too, but I think there is a lot to learn here.
For example I hae never used IGBTs before and already I hae begun to learn. This may also be a chance for me to learn to design a transformer that will work at 30Khz. I was thinking of using push-pull driver on the primay of the transformer instead of the flyback circuit. Something similar to a PC power supply. The Panasonic power supply is definately designed for constant current. The input current is monitored through a current transformer and this applied to the contol circuit so that a decrease in input current results in a greater output voltage through pulse width modulation. The plan is to take this feedback from a coil on the output transformer instead of the current transformer and apply it to the control circuit. I am hoping this will turn the constant current power supply into a voltage regulated power supply. Also the output rectifiers use a voltage doubler. My plan is to change this to a full wave bridge, I think David mentioned this too. I may not get full legal power out of it but maybe I can power a couple of 4cx250s. That wouldnt be bad for a $50 power supply.

Jimmie

If it's a flyback then push-pull drive won't provide enough voltage. In a flyback the E*T products of each half cycle have to be equal or the transformer saturates. You see a flyback transformer isn't really a transformer. It's a coupled inductor. The switch charges the core then the core discharges into the secondary. Current doesn't flow in both primary and secondary at the same time.

So the output voltage isn't a function of the turns ratio but of the ratio of switch's on and off times. A flyback with voltage feedback control regulates the output voltage regardless of the turns ratio. Other considerations demand more turns for high output voltages, mainly the secondary voltage is reflected to the primary and added to the input bus increasing voltage stress on the switch. The primary turns are determined by the factors effecting core saturation.

All this leads me back around to thinking it's a single ended forward converter with resonant reset into the seconday.

Even if it is some form of ZVS flyback it may be possible to convert the oven power supply to a voltage regulated converter with either a voltage divider on the output or a voltage sensing winding with fewer turns. Because the volts per turn in the secondaries are fixed by the control this works well. If the sense winding has 100 times fewer turns the voltage developed by it will be 100 times less. There are some errors due to imperfect coupling between the windings and the rectifiers Vf but these can be tweaked out enough to get the regulation down about 3% with some reasonable minimim load maintained.

There is another topology called a fly-forward that transfers energy during both the off and on times of the switch to the secondary. It's bascially a single ended forward converter that resets the magnetizing energy into the secondary in flyback mode. I'm convinced the oven uses resonant switching though so I doubt that's being used here.

The reason for the very small input filter capacitor is power factor. With the small filter capacitor the line current follows the envelop of the switch current. If the duty cycle is constant over a half cycle then the current waveform is determined by the line voltage and then you have nice haversines of current drawn from the line. If the voltage control circuit response is fast, then the current will be distorted. With a larger input filter capacitor the current will look like the typical uncorrected SMPS with a capacitor input and draw huge current spikes at the peak of the line as the capacitor is charged. Then you must draw less power from the line to account for the low power factor. The input rectifier might have to be beefed up as well and more agressive inrush limiting would be needed too.

I hope it's a forward converter then the transformer would be very handy. I may have to start snagging ovens from the curb side on trash day. I have a bucket full of 4CX250B (really, a bucket full) waiting for a home.

And yes, IGBT's rock.

Yea, but there's less and less each year as the old guys die off. I know
you work CW so you know that the vast majority of your CW QSOs are with
people in their 60's and over. One foot in the proverbial grave.

>This past Field Day, for example, the group I went with had one

I agree it's not a flyback.

I don't think it's resonant converter because you looky at VK3HZ's
data on loading it, the duty cycle would take it way out of resonant.

As for power factor with lots of input capacitor filtering, a double
pi AC filter
with toroids would smooth the fawk out of any huge SMPS input
capacitor filter.
When I put a triple pi toroid on the AC line to my 500 watt SMPS
computer
tower, what a big difference, knocked out all kinds of harmonics and

spikes.
And reduce my electric bill. Is that like stealing from the electric
co?

That theory doesn't hold water because Morse Code isn't obsolete on
the HF/MF ham bands. You hear a lot more hams using Morse Code on
those bands than you see people riding or driving horses.

A much more reasonable theory would be that most states do not test a
driver's ability to operate a manual transmission.
>
> >But even though the last remnants of the Morse Code test were removed

That doesn't seem to be happening. Groups such as FISTS and SKCC have
increasing numbers of members. Participation in contests using Morse
Code isn't declining increasing even with terrible sunspot numbers.
Look at the results of the ARRL 160 meter contest for the past several
years - and it's all-CW.

> I know
> you work CW so you know that the vast majority of your CW QSOs are with
> people in their 60's and over.

No, they're not. Sure there are lots of hams who are senior citizens
but there are also a lot who aren't - and who use Morse Code on the
air.

Plus the whole US population is getting older. People are living
longer and having fewer kids, for one thing. The median age for US
residents back in 2000 was 39 years and some months (according to the
Census Bureau). And it keeps increasing.

One foot in the proverbial grave.

How old are *yiu*? I'm 54, been a ham 41 years.

What led me to my theory is that the FCC didn't just drop the Morse
Code tests, they simplified and reduced all the testing as well as the
administrative procedures. For almost 30 years, every change was in
the direction of making less work for FCC, to save resources.

> >This past Field Day, for example, the group I went with had one

>
> You don't really call those guys with the computers and keyboards
> who ruin the CW bands on contest weekends CW ops do you ???

Why not? All the computer does is keep the log and maybe call CQ. The 'phone stations had the same computer logging system, all networked to a central server. Yet the CW ops outdid them easily.

As for "ruining the CW bands" - the only "CW bands" in Part 97 are the bottom 100 kHz of 6 and 2 meters. All the other bands where CW is allowed share the space with other modes, such as RTTY and PSK31.

It's just beautiful when the bands are full of hams making QSOs. Not "ruined" at all.

Thanks to jimmie for the PDF service manual; inspection of the schematics shows differences between the block diagram (which seems to show a resonant configuration) and the inverter detail schematic (which shows a voltage doubler configuration). There are also mistakes in wiring runs (circuit box outlines confused as wires and having cross-connect dots misplaced, etc.). After accounting for these, the above assumptions seem correct.

A quick web search for inverter microwave ovens seems to yield only Panasonic models, and the cheapest in my area is $158.00 at Walmart. To me, this isn't really cost-effective, and they are too new to be found in the alley. I intend to continue to explore utilizing PC PSU parts to build an HV supply.

Michael

The code may be fun to use as a *hobby* but it is obsolete
as in the dictionary definition: to become disused, old fashioned,
and no longer up to date.

The FCC (and the rest of the world) just recognized that
 requiring people to become human modems to
get a ham license didn't make sense. Maybe it did in WW2
 when a pool of human CW ops was needed, but certainly not now.

>Groups such as FISTS and SKCC have
>increasing numbers of members.

You won't win this one on the numbers. Do you really
think the number of active CW ops today compares
with the numbers there were in the 50s?

>Participation in contests using Morse Code isn't declining...

No unfortunately contests are just as bad as ever.

>the only "CW bands" in Part 97 are the
>bottom 100 kHz of 6 and 2 meters.

Playing word cop is not your style, sorry to see you do it. The
'CW bands' are common ham jargon not lawyer speak. Just as
using the term CW when you mean the code mode.

You'd think that now that no one is being forced, it shouldn't be an issue. Maybe the real problem all along was people who really have a problem with other people's hobbies. You people really need to quit bashing each other's hobby. What you screw around and loose for someone else, you lose too. Obsolete is a favorite word of the salesman that wants to con you out of what you have, to sell you something else. For better or worse. So don't buy into it. You need to understand that the FCC really doesn't want to be bothered with Ham Radio at all. That's been motivating nearly everything they have done since the 70's. But, Ok a bunch of whiners screamed and cried and held their breath and now even the Extra Class is code free. Doesn't make much sense because all you get is some CW subbands anyway.

All the Anti-CW arguments could easily be used against Ham Radio in general. I don't even want to hear obsolete. I still have a manual typewriter to fill out odd forms and in case power goes out. I still have a VCR because there are movies that I don't see on DVD yet. I even use CW on VHF and above to make contacts that can't seem to be done any other way. People scream about Digital! Digital! OK WHICH DIGITAL do you use. There are more than a dozen modes out there, so how are you going to make the contact that is gone in 60 seconds because of propagation? Let me know when you have a free software package that instantly decodes ANY MODE and doesn't even require a computer or extra hardware, is operable across all bands and digs weak signals better than CW, then CW will be obsolete. The fact that CW is allowed EVERYWHERE and can be received by any SSB RCVR make it a universal mode of communications. It is also the most useful means of station identification. Don't tell me it's obsolete if you don't know anything about it.

There is a rail system in India that was set up in the 20's and is still in use because it works so well for what they use it for. They would screw up a good thing to try to replace it with anything more complex.

The part can be bought as a spare for about $40 or $50 dollars.
I have found a couple of them at Goodwill. I would have be tearing
into it but our 20 year old microwave finally bit the dust so my wife
put claim on this one.
I have also seen them setting on the curb on trash day. On was on my
way out and thought I would pick it up on my way back in. Didnt work
out. Since I started looking for them it seems there are two common
reasons people get rid of old microwaves. One is to have the latest ,
greatest model and the other is because the digital display quits
working. Any sort of failure out of warranty usually means a trip to
the curb.

THESE MUST BE OPERATED UNDER LOAD OR THEY WILL SMOKE.

At least that is what happend to mine.

Jimmie

I'm sorry, I should have been more precise in my use of terms.

It's zero voltage switching or ZVS which is resonant transition.
The resonance is much higher than the swicthing frequency and it
isn't effected by the changes in duty cycle. Although it does
steal some on-time

Sometimes it's called quasi-resonant and there's a variant called
ZCS or zero current switching.

It's not a resonant converter like series or parallel resonant
converters where the output is controlled by shifting the frequency.

Oh, sorry to hear that. Yeah, it's a bad idea to operate any switch mode power supply without a minimum load unless the min. load is built-in or the thing is so inefficent that its own losses make up the minimum load. The output diodes probably didn't like that... just my guess.

I found some interesting stuff on the panasonic inverter.

On the fusor chat they claim it's 85% efficient and good for 1200W. The efficiency seems right, the 1200W seems... optimistic.

Also this, instructions on getting the inverter to play.
http://www.fusor.net/board/view.php?site=fusor&bn=fusor_hvpower&key=1162079046

I changed the header subject to better reflect the discussion.

"JB" <nospam@goofball.net> wrote:

> You need to understand that the FCC really doesn't want to be
>bothered with Ham Radio at all.

That's probably true.

>That's been motivating nearly everything they have done since the 70's.

I think that the ARRL had more to do with the snafu's of that era. For
example incentive licensing.

>now even the Extra Class is code free.

As is the free memorization EC exam. No real electronic knowledge
required to pass.

>I still have a manual typewriter to...
>I still have a VCR because...
>I even use CW on VHF and...

Typewriters, VCRs and CW are all obsolete by todays
technical standards. Some still use them because like
you and I they like to. That doesn't make them less old
technology. (Think horse/buggy analogy)

>OK WHICH DIGITAL do you use.

Head copy.

> how are you going to make the contact that is gone in 60 seconds

I'm not. I prefer CW ragchewing. Different strokes...

>Don't tell me it's obsolete if you don't know anything about it.

Got my Novice in 57. Been doing CW ever since. But only as a hobby since
it's obsolete and not good for much else...

So, I'm a young whippersnapper (42 y/o ... got my Tech+ ticket in 1988): Can someone, without adding TOO much editorial slant, explain what the 1970s push to incentive licensing was, and with as little slant as possible explain why it was a SNAFU (or as one 1x2 in the first club I was in said: Ruined the service).

Hey mule:
Your url got cropped.

The inverter PS I have can be fooled into thinking it has a load.

There is a current sense I found and a voltage sense
both on the primary side.
It's a piece of cake opto coupling a signal back
to those sense inputs. they are both straight voltage dividers
with Vrefs. And the current sense uses a 50K ohm trim pot for
adjustment.

They use a 100meg bleeder for a load. And the filament which is at
least
150 watts, loads the supply too.

I suspect my 120VAC inverter will work off of 240VAC

And if you take out the filament circuit that gives yoiu an extra 150
watts.
I suspect I can gits 1500 watts from my 1300 watt interer PS, with
input
filtering of the DC off the mains.

But the final report wont happen until i gits the feedback circuit

wired.
That will prevent it from trying to produce 1300 watts into no load.
With no load it will try to up the voltage to produce more current.
Which it can't
produce more current so it keeps increasing the voltage untill it lets
out the smoke,

When it hits 3000 volts I will fool the sense circuits: a voltage
divider for
the current sense and another divider for the voltage sense, into
seeing 1300 watts.

Another trick is to run the mains off a variac starting at 10 VAC very
slow. Also supply seperate power to the PWM IC circuit,
Just to see how far it will go, and not get it to go into run away.

I see the power trouble how can you gits 1300 watts out of that little
bitty core?
That's what they used to say about silicone diodes when they used to
replace a 5U4 tube.
They used to tell me how can a little piece of wire with a bead on it
replace a tube as big as your fist
no freaking way. I also made a living selling 2.5 amp 1000 piv diodes.

I mean the primary of this thing uses litz wire that looks like 10AWG
wire about 13 turns around the core
and they using 4 strands of 28 AWG to run the filament
The HV secondary measures only 6.8 ohms DC.

As I remember it...
I am not sure what the ARRL had to do with events previous to 73 and some of the chronology from memory.

The 11 meter ham band was taken away to make the Citizens Band in 58?   It didn't turn out anything like the FCC expected. Previously there were fewer ham license classes and everyone was on the same page. Also privileges were taken away from the highest class to make a higher ones. Ticked off a lot of Hams to lose.

The Technician License split ham radio into two factions by offering a license class that had little incentive to upgrade and actually made it much more difficult to, by limiting the opportunities for on-the-air training. People who took the Novice ticket were upgraded to General in less than 2 years or never got around to get on the air and let it lapse. Hams (in my area anyway) were expected to build something as a right of passage. Building a code practice oscillator would get you a pat on the back from everyone and you were in with the simplest project there was. I built that and the power supplies for my mil surplus rigs. Some guys built a whole Novice station. Techs at that time were expected to retune or modify a rig or some project as well but would go straight to CB like intercom operations not conducive to learning the HF skills for upgrade. In my day we were aware of a difference but we were all brother hams then. I had Elmers that were Techs and beyond. Most all were technically inclined enough to have built something. People were generally civilized and knew that we were all on the same team. If there was irritation between individuals, and there were oddballs, it was downplayed for the good of amateur radio, because it was a small world and people were listening. And you would run into each other again and again, so no sense carrying a grudge.

That was the reality of it, whatever your point of view of how it should have been.

In the late 70's there was a push by ARRL to get CBers interested, and over the counter 2 meter radios were first becoming available.

ARRL didn't seem to understand that CB was a different service with a different mindset and many were already set in their ways.   They seemed to be willing to get people to hang outside of RS stores and lure CBers under false pretenses about amateur radio in order to pump up the license roles and subscriptions to QST.   Wayne Green was one of the ticked off ones and started 73 magazine to rag about the ARRL and QST. ARRL also convinced the FCC (easily) to set up the volunteer examiner program. Novice exams were already given by volunteer Extras. FCC wanted to lighten their work load since Ham testing and licensing was taking up most of a day at the field offices.

License renewals were then made easier and for longer. ARRL liked it because the rolls didn't drop out so fast and FCC didn't have to bother as often.

The volunteer examiner program gave seminars to get people licensed but because of the accellerated pace, people got licensed before they got a chance to learn the realities of getting on the air and keeping a station up and meeting the people. Some people would find it not their cup of tea and leave but their license was now good for 10 years pumping up the rolls.

The no-code Tech license 83? further divided amateurs and even further sidetracked Techs from upgrading. Lead time for getting a ticket was shortened from the 2 to 6 months or so to learn the code to as little as 6 weeks, then 2 weeks as the process refined.   It was notable that in the 80s, there were many who learned the code anyway and upgraded but the whole thing by and large tended to split Ham Radio into those who upgraded and those who couldn't very well.and were often frustrated. Many would tell themselves they just weren't interested and resented the others. Way too sad. I finally came to grips with the idea that they should do away with the Tech class license at all costs, even getting rid of code testing for the General to do it, just so we could mend the split.   I was stunned when they dropped the code requirement for Extra though. I really haven't kept track of all the current structure since I got my Extra in 93.

In any case, the "incentive" licensing structure was anything but incentive. So much for good intentions. ARRL has done a lot of good things but some major screwups too. Support them but keep an eye on them and keep them straightened out.

>Can someone, without adding TOO much editorial slant, explain
>what the 1970s push to incentive licensing was,

Shamelessly copied from: http://ham-shack.com/history.html. Check here for the history before and after the event.

"1967-The FCC announced the new Incentive Licensing rules: over the next 2 years, General & Conditional operators would lose 50% of the 75-15 meter phone bands, the "First Class" idea was dropped, the Advanced Class was reopened to new applicants, Extra & Advanced Class operators get exclusive subbands on 80-15 and 6 meters, the Novice license term is doubled to two years, but Novices lose their 2 meter phone privileges, the FCC restates the "Technicians are experimenters, not communicators" policy, and states that the next license step for Novices is the General, not Technician, class."

>and with as little slant as possible explain why it was a SNAFU

That SNAFU of course is a slant by those of us who lost privileges in the new licensing system. I was a General at the time. I actually had to buy a Bash book to get them back...

Hmmm, first time I've read such an opinion regarding original Techs; in my experience, Techs concentrated on building, experimenting and exploiting VHF, UHF and above and had less inherent interest in HF. Some were just unable to muster higher CW wpm for other tickets.

Perhaps you are referring to later model Techs; the term 'Elmer' didn't exist
during the day to which I refer.

Michael

Look in the letters section of a 50's QST, there's rants and raves
```

from both sides on incentive licensing.

Look in the letters section of a 60's QST, there's rants and raves
from both sides on incentive licensing.

The controversy in the 70's was the Technician license, a ticket that
required no code, as a way to get some CB'ers to take notice. I myself
came to ham radio in the 70's but had no interest in anything having
to do with Technician privileges. I know many other hams who did come
in that way in the 70's, 80's, etc.

Tim N3QE

Of course there were variations in your experience depending on the crowd
you fell in with. To this day, the club experience tends to be limiting for
those who want to explore in depth, the great variety of interests that ham
radio has to offer. There are in fact many, many specialties and
sub-interests within amateur radio. If you try to list what they are, you
keep adding to the list indefinitely. Clubs tend to promote the entry and
political interests and get preoccupied there. If people in a club are
ragging about lack of Elmers or Technological interest in ham radio, it is
because the club itself has become stagnant with a lack of imagination, like
the teenager who sits around watching TV and complaining about being bored.
Boring people actually bore themselves. In my experience, most hams don't
show up at the local ham club because they have other Ham Radio interests.

Your Experience (above, re: Techs vs. HF) is proof of what comes of
promoting a division within ham radio. Politics should have learned by now
that the 2 party system has become the same kind of disaster. The Electoral
system used to have several parties and candidates and the winner became
President and runner-up was Vice-President, regardless of political party.
Probably more aggravation for the cabinet, but more of a stabilizing
influence on our nation. Our current system has actually promoted a rift in
America that gets farther apart as we go our separate ways in order to avoid
drowning in the middle. Eventually this could lead to another Civil War but

I digress.

An Elmer was everyone who was willing to share what they had learned. The term and the people were there long before I decided to be a ham, perhaps pre-war QST. The first thing I learned was that with so many sub-interests, the only way I could hope to experience it all was vicariously. By visiting the garages and hamshacks to see what other people had done. Antenna experimenters, transmission line specialists who conversed with Smith Charts. Teletype experimenters who were cobbling home made digital controllers to their model 28s, that would become the home computer. People who did various mods and projects involving existing equipment, People who built their own equipment. Even one poor kid in High School who built a full QRP station onto his bicycle from transistor radio parts and other junk. This guy had a bit of an inferiority complex, because when he would show people the construction and circuit designs (often modular with junk boards modified and cabled together in a re-used cabinet) they would become very interested and of course the "why did you do it this way" question would always set him off. Some would joke him over that. I had to remind him often to put away his anguish and realize they were in fact impressed by his accomplishments and what was happening was in fact a by product of their curiosity and envy. Although I was an Advanced and He was a Novice, it didn't change the fact that we were both Elmers in our own right. We become Elmers to each other as long as we don't pout and cry over normal human relations.

I realize that pouting and crying over normal human relations has become some sort of fashionable thing lately. I don't think it is a good thing. Maybe it is from people being told by their Psychiatrist (like Cops, depend on repeat business) that everything will be OK if they let their emotions take control, and that it is perfectly normal to throw tantrums or hump people's leg in public. Makes good press though.

So it was FCC after all that formed the opinion. Sounds like a conspiracy
theory to keep us preoccupied with infighting.

Forgive the top posting - note the interpolations.

On Aug 26, 10:43=A0pm, Syl <s...@somewhere.else> wrote:

> Thanks. Several of those specs do bring questions though as they aren't properly defined (unless they are in the full FCC documentation ?

Well, not really - what the FCC requires is apart from many of the specifications shown. Example: US Federal requirements on automobiles write to certain requirements - leather seats is not one of them. Part

15 writes to certain requirements - Accepting stereo inputs, broadcasting 20hz - 20khz, and very low distortion are not amongst them. They are the leather seats.

> a) Just what "very low distortion" means ? To me, very low distortion would be 0,001% as a minimum. But I understand that in the real world of transmitters, 0,1% is probably considered very low distortion figures ? This based on the presumption that attaining 0,001% distortion figures is easier to attain than using tube technology. Correct me if I am wrong.

In the specifications - which you have to dig further into the site to find. However from my discussions with Phil, that VLD is relative to most commercial broadcasters and also a function of the much broader bandwidth.

> b) Adjustable compressor/limiter. To what levels ?

Also in the specifications.

> c) High Quality PC Board and Components. Does this means the homebrewer can't use Chinese made parts [grin]

I am not so sure how to answer that question. I have seen homebrewers use the functional equivalent of Venusian water buffalo poop in their rigs - as long as it meets the radiation requirements of Part 15, I am not so sure the Feds will care. Phil sources his parts from all over the place - but many of the custom parts are made locally - not in China.

>
> Of course I do not mean to start a discussion on these points, merely thinking out loud...;o)

You mean that you are not taking a page from Mr. Byrns' book and attempting to poison the waters around what should be a pretty simple discussion? ;-{ 0>

> But...I now better understand the requirements for part 15. As It shows, the only difference between a commercial unit and a homebrewer's is the latter does not have to pay labs testing and approval for his "concoction" whereas the former (the manufacturer) has to have the FCC seal of approval and the of course the onerous fee(s) along with the approval tag.

Something like that.

> I wonder how the FCC manages the homebrewer's "concoctions", other than reacting to complaint(s) ? I suspect this is what happened to the kit builder whom got fined sometime ago ?

Basically, the FCC (as it is presently constituted) is a dumping ground for political hacks owed a small favor and the sons of wealthy political hacks owed a larger favor. There is not a scintilla of competence throughout its political-appointee management and hasn't been for perhaps the last 6 - 20 years (maybe much longer), depending on whose ox was gored most recently. For the most part, its regulations are written so vaguely that the adage "Money talks, the rest walks" covers their behavior. The individual who was assembling SSTRANs for resale got fined by the FCC because a competitor selling a fully-assembled product WITH the FCC compliance certificate at over 10X the cost felt threatened and injured - and had the money and was paying the fees to get action.

It is interesting to note that said kit-builder is back and has done the thing he should have done in the first place to be in full compliance with Part 15 (not sell assembled transmitters) yet still perform the service for his customers - so simple and so obvious that he missed it for years and was fined. He is now bullet-proof in that sense. Care to guess how he is doing it?

Put it this way, every single solitary AM transmitter *KIT* sold in the United States today for single-house use from Vectronics to Ramsey to SSTRAN to the L'il 7 et.al. that calls itself "Part 15 compliant" is subject to the same regulations. It is my opinion based on my experience with most of them that the SSTRAN happens to be the most convenient unit to use and short of a parts-box home-brew represents the best value-for-money in addition to its convenience. That Phil is a distant neighbor and a decent guy does not change any of that.

As the "other" Phil notes, the FCC reacts to complaints. If the complainer is of the party-in-power and also has money may affect the speed and effectiveness of their response - though not necessarily.

Part 15 Compliant is one of two possibilities.
#1.. Transmitter is actually FCC type accepted... read EXPENSIVE PROCESS

or

#2.. Home Built or Kit Built unit for your own use... but still meets
the requirements of 100 mW and antenna etc etc etc..

Both #1 and #2 above must NOT interfere with commercial services.

Again Both of the above would only be investigated by FCC if complaints
were filed.

The Guy thats back to building the kits again ... this time legally is
probably still leaving the unit in a somewhat "Kit Form" requiring
enough final construction to the end user to comply with FCC rules.

Dunno how he does it but
the way "I" would do it is build the kit for free and get the
customers to pay for an irrelevant item (say a label) for the whole
cost I would charge building the kit, or better yet, have the customer
install a few parts by themselves and send the kit in for repair
'cause it doesn't work...

Much like those selling pirated CDs from well known "free movies"
archives and not charge for the actual CD content but for the labour and
material cost...

Syl

You want to wade through CFR 47, part 15. That has the laws the FCC is supposed to enforce.

Yep.You are on the right track - the kit is built all-but-plugging the
chips into the sockets. That is left to the customer and apparently
enough to satisfy the regulations.

Ah, well. I built mine and I enjoy it nearly every day. I also keep an
FM-stereo transmitter so I can feed AM signal to the vintage audio and
FM signal to the vintage radios...

Hey, does Little Vinny have any currency from the middle east? I could
gather a few coins together if you wish?

finally came across an article by VK3HZ that describes how to make a
microwave oven inverter PS work, as a stand alone supply.
the link is:
www.users.bigpond.net.au/dwsmith/hv_inverter.pdf

It's only regulated from the primary side. And you can make it put out
anything from 2000 to 4000 VDC. but at 1300 watts.

So all I have to do is load down the primary to fake out the regulator
into seeing 1300 watts, Or run class A.

The output or the input still has to be filtered

There's an opto coupler that has to see a 110hz square wave, according
to VK3HZ, that'll keep the supply running full tilt as long as there
is power supplied to the inverter.

Well, I beg to differ with you about the (main) reason the frequency
changes.  Consider what happens if you have two coils magnetically
coupled and you monitor the inductance of one while you apply a short
across the other one.  Then consider what you'll see on the inductance
meter as you change the coupling between the measured coil and the
shorted one.  The references I've been able to find so far suggest the
permeability of brass is slightly higher than that of air, but I
suppose it's a function of the composition of the brass; in any event,
I'd bet that the shorted-turn effect is very much larger than the
```

permeability effect with respect to changing the inductance of the
oscillator coil.

Cheers,
Tom

I agree, except Air has no permeability, you can't magnetize air. You
can't magnetize brass. What you have is a proximity detector. aka
metal detector.

I think you're confusing permeability with susceptibility. Even vacuum has non-zero permeability.

I'm still considering Tom's points. What I know from decades of experience, is if I put a brass slug into a solenoid, the inductance goes down by a little bit. "Little" is relative to the effect of a ferrite slug, which makes inductance go up by a lot in comparison.

The "little" is key for the PTO designs I mention, it allows rather fine tuning with very simple mechanicals. If I think of it as shorting turns as it moves in, that is completely out of whack in my head with the observed changes, because shorting all the turns causes a big change in inductance, not a small one.

Which of course is why you see iron core and ferrite slugs in high inductance coils, but in small inductance, like you'd see at VHF, the slugs were brass.

Or, that tuning wand with some sort of ferrite at one end and brass at the other, so you could tell whether the tuned circuit was too high or too low.

At that level, brass and ferrite were seen as the same thing, a means

of varying the inductance. The choice was made by how much variation
you needed, and which way, rather than what action was taking place.

If the circuit can be driven from 555 osc perhaps the pulse width can
be controlled from a feedback voltage taken off the output of the
power supply.
I am thinking adding a small winding to the transformer rectifying and
filtering it and supplying this back to control the pulse width of
your osc.

Hi Tim,

OK, a 'speriment for you, and another way of looking at it that will yield the same result:

Make two "slugs," one solid and one hollow. If it's permeability that's doing it, the hollow one (with thin shell, of course) will have considerably less effect. If it's the "shorted turn" effect, both will be about the same.

Consider that there is no time-varying magnetic field inside a shell made out of good conductor--really zero if it's a superconductor, but dropping to practically zero after a few skin depths. So you are removing a volume of magnetic field when you put a conducting slug in the coil's field. With less field, there's less energy stored, which implies lower inductance. The same thing happens when you put a coil inside a shield-can: the inductance is reduced. A points that seems to be not well known: the unloaded Q of a helical resonator is less than the Q of the same coil that's not inside a shield. There are graphs available to determine the lowering of inductance by a cylindrical shield around a coil.

Cheers,
Tom

Yuri, K3BU and MountainView Resort in Glen Spey, NY are hosting Labor Day Party with BBQ and live music on Sunday August 31, 2007 at 2:00 pm at the Ardmore Mansion. Special table reserved for Ham Radio aficionados. Check out this enchanting location for the future HamConvention NE. Come and tell the lies and have a great time.

Our famous All-You-Can-Eat Gourmet BBQ
Dance or enjoy the Music of the "Udech" band
Have a great time for only $20/person
Cash Bar: Beer, Wine, Drinks

Come and see the newly renovated
Ardmore Mansion at MountainView
The elegant choice for your wedding,
banquets, retreats & special events
and bring a friend!

Weekend camping at the lake.
Rooms available for rental, call for reservation.

For more info and color poster please see
http://www.mvresort.com/events.htm

MountainView resort, 369 High Rd., Glen Spey, NY
Tel. 845 856-1105
Please contact Yuri, K3BU@optimum.net or cell 973 220-0087 for space reservation.

I was the OP of the origonal thread about the inverter power supplies.
I was actually more interested in learning about the design of the
power supplies so I could possibly build one from scratch. With the
right information this may be easier to do than to modify one from a
microwave oven. I am very grateful for the information. I have a
couple of the Panasonic power supplies unfortunately they dont work
but maybe I can repair them now that I have a schematic. Information
on the transformer would be a good thing to have as I am sure it could
be optimized for the desired output voltage and current needed for an
amateur amplifier.

With the current transformer on the front end I am guessing this may
be the feedback path for regulation. That is to say the power supply
is being controlled by the amount of current that is being drawn on
the input side of the power supply. If this is the case maybe this
input can be taken of the out put of the power supply and then the
supply could be voltage regulated instead of being power regulated.

Jimmie

The definition I found for:
Permeability (electromagnetism), is the degree of magnetization of a
material in response to a magnetic field

In this case 1 means no permeability.

I agree Tom
It's not permeability that changes the inductance it's the mutual
inductance that is changing the inductance.
Any metal brought near a coil acts like another coil. If that coil is
out of phase. Then the inductance is lowered.
So with brass it's not the permeability it's the inductance of the
brass slug and the mutual inductance of the 2 coils that varies the
total inductance, of the main coil that the brass slug is in.

Towit a brass slugged adjustable coil is just a variometer.

Kind of a variometer with external connections to only one of the
coils and the other one shorted out, I suppose. ;-) If you have an
actual variometer with two coils you can put in series, you can get
significantly more inductance variation than with a brass (or copper)
slug. In the case of series coils, you can both add and subtract:
you get the sum of the self-inductances of the two coils, plus OR
minus the sum of the mutual inductances. If the coils are tightly
coupled (not particularly easy to make, mechanically, for one coil
rotatable inside another...), the mutual inductances are nearly equal
to the self inductances--so for example if k=3D0.8 max and the coil self-
inductances are 1uH each, you can vary between 0.4uH and 3.6uH total,
a 9:1 variation. If you could manage to squeeze k(max) up to 0.9
through some heroic effort, you could go from 0.2uH to 3.8uH or 19:1
variation, enough to tune a tank over a 4:1 frequency ratio. Q isn't
very good with the coils opposing, though, since you still have the
same copper losses as when the coils are aiding.

Cheers,
Tom

Is it a plastic bodied component? Does it have one terminal at each end?
If yes, I'm guessing it's a diode.

hi joe thanks for your response.it has 3 pins on one side and on
thicker pin like a small heatsink looks like this
http://tinyurl.com/5ltz2j
i'd appreciate any help on where to get another or an equivalant.i've
looked through shed loads of smt code books online cant find same
code.i've tried contacting kenwood????

thankyou

Ahh, so its a transistor

Do you have a schematic? Is there another transistor with the same markings?

A lot of times transistors are pretty generic and you can throw in "any old thing". If that is the case, you should be able to tell from the schematic. If not, and you have another, perhaps someone has a semiconductor analyzer and can measure the parameters of a good one, and then you can figure a replacement based on the parameters.

Of course, you would hope that Kenwood would be anxious to help

It could be a transistor as the other poster mentioned, but it could also be a voltage regulator IC. Your best bet would be to obtain a schematic and/or parts location diagram for your radio to help ID the component. Then your next stop would be Digi-Key or Mouser to look for a replacement.

Also, try to determine what caused the part to fail before installing the new one so it doesn't meet the same fate.

-Joe

The OP did not mention the handheld radio model ,other than it is from
Kenwood. An instruction manual with circuit diagramme(s) of the
relevant radio can highly likely be found at : www.mods.dk

Hey Jimmie

I suppose that you could use the duty cycle feature of this supply to
control the output
but I'd need a bank of 450WVDC caps to supply filtering.
So say the power of the amp drops: the supply will compensate by
increasing the voltage
But with feedback I could drop the duty cycle thru the opto coupled
input. Thus causing a drop in voltage which the filter would handle.
By running the inverter at another lower duty cycle I can control the
output voltage.

I would suggest at least a bank of 16, 450WVDC for a little head room.
Plus that would take out the 120 cycle ripple.

hi,
thanks to all responders .there are three on the same board.the model
is a th-26 handheld 2m.i've checked all the surrounding resistors and
nearby passives .i think its a power supply problem.i dont want to
power it up yet until i find out what this part doesi dont want to take
another one of these ants lol out and check it out of circuit.smt is not
my thing.i've searched for a free schematic so if anyone out there's got
the schematic that'll be great .i'll take on board what you guys have
said many thanks for taking the time.

More than likely your talking about a transistor maybe a mosfet
The center lead is the collector or drain.
Look for the same numbers on other parts
and measure the forward to back ratio. To determine the kind of
semi it is. should be quite ez. Mostly they using transistors like
this for switching or buffers
so I don't think it could be a darlington.
It's either a npn or pnp.
less likely a FET n channel or p channel
It could still be a zener or a dual diode
Zeners they connect the 2 leads together
And a dual diode will have the same reading on each junction.

Thats pretty much my idea.
In radars something very similar to develop 6KV to charge the PFN. If
you could analyze the circuit where the current sample is picked off
the AC mains that would tell us a lot about what would be needed to
develop the proper feedback signal off of the switching transformer.
Unfortunately I am without power supply at the moment. Well I have one
but my wife has forbid me to touch it. That is her primary cooking
device As Dave idicated the rectifiers for the output of the pwer
supply are configured as a doubler and it could be configured as a
bridge if you wanted lower voltage. I am thinking maybe(a lot of

supposig here) this thing may be configured from 1500 to nearly 5kv by using a combination af feedback adjustment and rectifier configuration.

I agree with about the caps,

I emailed Dave and he pretty much agrees with my idea at least in theory but he has dropped the project at least for now.

didnt you say you had a source for these power supplies.

Anyone who gets this to work would surely have some serious ham radio bragging rights.

Jimmie

The Service Manuals are available either as a free download from various places or can be bought online and shipped overnight for a decent price. All I have seen have extensive parts lists and detailed schematics and board prints. You head needs to be there if the part is unknown. It could be bipolar, fet, or even a regulator. If you don't know what model radio you have, why not?

you need to do it logically and scientifically, which is the basis of our hobby.

1.Get the service manual.
2.Get the part no, try Kenwood, if no go, then
3.Look at circuit diagram, identify component, replace with similar - its unlikely to be critical.

I suspect you are out of your depth at this stage in your amateur career, and perhaps it would be wise to seek the help of a local technician or knowledgeable amateur - your local club could probably help with contact details...

Andrew VK3BFA.

Have a look at www.mods.dk
Manuals ----> Kenwood
TH-26 Instruction Manual .zip
TH-26 Service Manual.zip

You can only download 1 manual within a 24 hrs period unless you make a
donation towards maintenance of the web site.
So 1 manual today ,another manual tomorrow ,etc

I am looking for some Heterodyne conversion crystals for a receiver I am making.
The frequencies are: 5 MHz, 7 MHz, 10.5 MHz, 13.5 MHz, 17.5 MHz and 21.5 MHz.
The variable mixing frequency will be from 3 to 3.5 MHz. I would prefer all the same type holder.

Hey Gary,

Rocks aren't cheap here: http://www.icmfg.com/thruhole_crystals.html
Maybe in 9 land they pave the streets with gold.
Personally I'd go with a programmable divider or PLL.

Maybe you like retro, then I'd get some old rocks the ones
you can take apart and grind them down to git's the freq's you need.
I recall grinding some of these to get them into the novice band back
40 yrs ago.
And putting a pencil mark on the quartz to get them to go down in
frequency.
FT243 style can be found here maybe still: http://www.af4k.com/crystals.htm

Gentlemen and any Ladies,

I have a National NC300 that I will be restoring. Were there any popular mods to this radio? Also:

Are there any particular problems like a known arching wafer switch?
before I get into this exciting restoration project?
What other Hints and Kinks should I be aware of?

Thanks in advance,

Paul P.

The Si570 will generate those frequencies, apart from the 5 MHz.

And you can't grind them unless they are quite close to the desired frequency. Grinding by hand will be too uneven, so the crystal will stop working if you try to grind it more than a tiny bit.

It also relies on a big stock of crystals spread around so you can find one sufficiently close enough, something that did seem possible in the years after WWII, but after all this time attrition may have reduced the stock considerably.

And realistically, they also have to be bulky FT-243 holders, since those you can open by removing screws, and the blank is held in place with pressure. More recent holder types require desoldering the case, and figuring out how to remove the blank and then get it back in place when it's soldered in place (or something like that I can't remember how the blank is connected).

One of the odd things is that if one has to buy new crystals, a synthesizer will likely be far cheaper. In the early seventies, synthesizers made a big splash because everyone wanted lots of channels on 2m FM, and the need to have them ground to frequency (and to equipment) made it all very costly, so synthesizers despite their cost and bulk became the norm.

Almost forty years later, a synthesizer for a handful of crystals would still be comparatively bulky, but would be even cheaper than in the early seventies.

Of course, 5MHz is the one in the bunch that is bound to be easy
to get (and if it's not, 10MHz makes it almost as easy) and
would provide the clock for the synthezier if it needs an external
one.

My personal experience is an FT-243 crystal's frequency can be
increased by several hundred kilohertz through grinding. A more
abrasive media is needed for the slurry than scouring powder can
provide. Permatex 34A valve grinding compound works FB. Most of my 80M
rocks (26 between 3.5 & 3.6 MHz) were originally cut for 3237 kHz.
Many of my 40M crystals were moved several hundred kHz as well.

The key to grinding is not to try doing too much at once. Let the
abrasive do the cutting, no downward pressure is need from the
fingers..

There are still a lot of them out there and they can be most

inexpensive if the actual frequency isn't too important.

All this discussion about crystal grinding is very interesting. From my
far distant experiences, it is indeed a work of art and, more often, an
act of God. If the OP goes down that route, he may never actually get
his receiver built!

Looking at the websites of various manufacturers/suppliers (Google on
"crystal+frequency" and similar), it looks like you should be able to
get custom-made crystals in the required frequency range for less than
$20 each. I'm sure that at least the 5MHz will be available
off-the-shelf for less than $5 so we're talking maybe $100 for the six
crystals.

The alternative is, as has been suggested, a frequency synthesizer.
There are countless circuits available, but care should be taken to use
one where the spectral purity of the output signal is adequate for use
in a communications receiver. In particular, the phase noise has to be
low. One approach would to be look for a kit with a good spec (and
obviously something as simple as possible). A Google on
"frequency+synthesizer+kit" and similar brings up lots of information.

A hundred dollars can be quite a bit, likely the rest of the parts aren't that much (unless someone is buying all new parts).

The thing about a synthesizer is that the original poster only needs well spaced frequencies, so the reference frequency can be 500KHz, which allows for much easier filtering than narrower channels (or, the early synthesizers in the seventies that replaced 8MHz crystals in 2M FM rigs, not only did they have to deal with close together channel spacing of 10 or 15KHz, but since the synthesizer output would be multiplied up by the transmitter, the reference frequency was the channel spacing divided by how much the transmitter multiplied, which gave a terribly low reference frequency.

Plus, these are for changing bands, not tuning a given band. A second or so of lockup time isn't a problem since changing bands won't happen often. So the filtering can be better without impacting on tuning. A main tuning synthesizer with 1KHz steps starts out more complicated because it's 1KHz steps, but then it has to change frequency rapidly, which makes it even more trouble to design well.

What ever happened to that neat list of surplus crystals that JAN
in Fort Myers used to offer? Those were the good old days.

A few of those crystals are available on the Surplus Sales of
Nebraska website. I find two rocks I needed (1.515 kHz for
2nd conversion from 1.6 MHz to 85 kHz) there after searching
for several weeks.

Pete

Believe it or not I was making a living sell rocks HI HI back forty
years ago.
It was like there was a freaking crystal company on every corner.
There was so
much competition back then the prices was chump change. The crystal
companies
could have put the big hurt on PLL or programmable dividers. I know
the real
reason crystals took a back seat, and it;s not what anybody thinks
happened.

Well I still use a kenwood 820s and it goes fine. In fact I'm just
putting the WARC bands into it.

The only parts I would be really concerned about are the 450 vot electros in series acroos the 800 volt final ht supply. If you were very careful a good look at the caps smoothing the 300 volt screen and driver plate supply might also be a good idea. If you do a search on google you will find all the tech data you might need including circuits and manuals. It's a pretty good rig except for some poor final tank design on some bands. a rewind of the Pi network inductor can help a lot and the use of the proper values for a working Q of 12.

This can give you up to 25 or 30 watts more output on some bands with no more DC input. It also saves you finals a lot of potential grief. See the QST 1983 upgrade article for a few ideas.

I've been racking my brain trying to figure out a reason.
But, I think you hit the nail on the head. It fits right in
with the obsolescence of the FCC 1st and 2nd Class
Radiotelephone tickets.

Pete

They may as well have done away with the FCC tickets. I passed the 1st class test at 22 years of age in 1972 on the first try for the ticket. I had never seen a TV transmitter, but had the ticket to work on them. Maybe years ago it was differant and a harder test.
Thought I wanted to get into the 2 way repair business, but never did. When I took the test it was only one dollar more for the first class, so took it and passed.
Most of the tests are made so any idiot can pass them.

Well Eico uses a 7360 as a balanced modulator in my Eico 753. When it
comes time to replace it I'm going with the TV set version, 6LE8 used
as a chroma demodulator. I see the 6JH8 has an extra grid. I know you
can use it but you are going to have to play with that extra grid it
may not just go to ground, like most suppressor grids.

Transmitters don't worry about noise figure or dynamic range...
I'm more worried about how the different gated beam tubes will
work in receiver applications.
Regarding your proposed mod, check this
website:http://members.shaw.ca/pacifictv/cartridg.htm
The 6JH8 can be used in lieu of the 7360 by following the
pin layouts shown on that page, as was done by Swan.

I caught that point in your original post.

There were plenty of articles about using the other but cheaper tubes similar to the 7360. But I'm not certain any I saw used them as a first mixer. One could go back and check. And if that's the case, either everyone just copied Squires 1963 article, or there actually was a good reason to not use the cheaper variants for the first mixer.

Hi Micheal

Most of the magic seems to be being able to generate push-pull LO
injection for the deflection plates, that along with the P-P output tank
balance, is critical for max. signal rejection at the mixer output. I do
have
a 1600kHz daytimer next town over (1st IF is1600 kc.)

I was thinking of using a trifiliar wound balun, driven by a cathode
follower
buffer of off the first LO, to provide the 3 volt RMS injection to the
deflection
plates. That should provide balanced drive voltages to each deflection
electrode?  Squires never provided a lot of
detail on his coils or how they were made.  A balun might provide a modern
solution for balanced P-P injection from otherwise single ended LO sources.

Pete

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

Has anyone used a GU-81M in a homebrew linear? I like the idea of building a quiet linear and this tube looks like it should do the job.

I've found very little info via google apart from a few wildly different specifications.

Back in the 1960's, Pat Hawker, G3VA reported (Amateur Radio Techniques, Pat Hawker G3VA, 3rd ed, RSGB, p83) that Brian Booth, G3SYC (SK ca. 2003), had used the 6JH8 beam deflection valve instead of the 7360. Brian compared the two devices:
i) 6JH8 has a good deal more linear transfer characterisitic
ii) 6JH8 operates with the deflector plates at 0 volts, ie unnecessary to bias to plus 25 Volts as per the 7360
iii) roughly similar transconductance 4400micromhos vs 5400micromhos for the 7360

iv) 6JH8 has double the anode dissipation (3 watts)
v) then as now the 6JH8 is significantly cheaper.

The final comment was that Brian had used the 6JH8 as a receiver mixer and also successfully as a mixer in transmitter circuits.

Great info, thanks! But I wonder how he achieved DC balance with
the deflectors set for 0 volts?

Pete

I am looking into making a kit based on the Small Wonder Labs Rockmite
(http://smallwonderlabs.com/Rockmite.htm) designed to be a wearable
short-range CW rig. My thought is to be able to wear it on an armband
like joggers do with iPods. Anyway, I need to find some pretty

specific parts, but I am having trouble finding them on Mouser, etc. I was wondering if perhaps a more experienced parts-hunter might kindly assist me in locating these.

My plan is to have everything except the earbud fit into/onto the chassis- 9V battery, telescoping/rubber duck antenna, and two pushbuttons for the key. Here is my list of parts that I need help with:

* 'key'- Rather than have paddles that stick out, I think it would be cool to use two pushbuttons on the top of the case, oriented so that you can press them while it's strapped to your other arm. My problem is that I need really shallow switch housings- my hope is to put this inside a pair of altoids tins attached back to back, and I'd really really like it if the key was more or less flush with the top of the chassis. I tried to surf Mouser, but there are kajillions out there and I can't seem to find something like this.

* control switch- see comments about about key, but I wouldn't mind if this stuck out a tiny bit.

* antenna- OK, so the final transistor is a 2222 at less than 1/2W. Does impedance mismatch even matter here? The obvious problem here is that I'm using HF... maybe I should use a ferrite loop? Can I even transmit on that? I'm really not looking for long distance here- maybe a mile or two. Any suggestions?

* volume/power - I was thinking of using Mouser 311-170-1-1M for the audio pot / power switch, but might there be a part that would be easier to mount? I'm guessing not, since I really want it to be a thumbwheel, but I thought I'd ask.

* frequency- Finally, since I'm not designing this system to be used long-range, maybe I should pick a really obscure frequency? What do you think? On one hand, if I used something in 80M, I would be unlikely ever to interfere with anybody, but that makes the antenna even more useless! Or should I pick 20M, maybe in the phone band? Please don't doubt that I will be very careful to ID legally and make sure to listen first, etc. But I just wanted to check...

Thank you for your time,
Ross Tucker, NS7F

I actually used a microswitch from the junkbox for a handkey for several months when I was just getting back on the air after a move.

What you describe sounds like an ergonomic nightmare though. Try 144.200 or 432.100 MHz the multimode calling frequencies. As long as you have a working RX you should be OK. You could drop it down to 100mw and probably still make contacts. There would be serious difficulty coupling 80m energy without an antenna unless you were considering a 135' trailing wire.

I always wanted to build a Get Smart shoe phone or better yet the Star Trek communicator. There was a 73 magazine with one. Lots of fabrication just like the original. It was THE prototype for the now common flip phones.

I never could find the little rotary dial for the shoe phone. I am extremely overjoyed to see the Get Smart reruns back on the local independent station.

My first "HT" was a 1 watt packset radio (Mot H23BAC) with about 5 submini tubes. The RX strip would run about a week on a 6v lantern battery, but there was only about 30 minutes talk time for about $20 worth of batteries for the transmitter. The answer was to build up a solid state FM TX to sub in for the tube strip to run on several surplus SubC Nicads. I lugged that around for several years. I finally got a HT220 Slimline that replaced it. Those were the days when repeaters were a new thing and everybody in town was on the one frequency.

I don't know if you noticed the OP-ED piece in QST from the newbie... Shouldn't we all be building a portable transporter units or time machines instead?   We are all obsolete he says. I wonder how long before he has a meltdown and QSY's to his Blackberry.

I have a few transistors(I think) I am trying to identify.
They look like stud mounted SCRs with a 1/4-28 stud but the ohmmeter
says they are NPN transistors. They were in a bag marked "servo amp
transistors" no ledgable markings on the transistors. Any suggestions
as to which type they maybe.

Jimmie

M cubed makes a nifty tester that automatically identifies the leads, type
(NPN etc) DC beta , leakage etc.

Many thanks, that gives me enough info to get me started. I plan on using it for RTTY contests, I have an amp using the 4cx800 but the blower gets to me after a few hours. With the price of 3-500Z in my main amp getting silly this looks like the ideal cheap tube to use with the PSU from the 4cx800 (2800V), just bought two of them on ebay for $60 the pair + one socket. I probably wont need the spare as he's had 12 years of contesting out of a pair.

Steve H

Hello Everybody,

My new radioamateur site is running in BETA state, the url is:

http://ha0rex.freehostia.com/

Now working: DX Cluster (now in Live!), Online Log, Users profile, the Forum is coming in some days.

Most of the functions are accesable after registration, what is simple and easy.

73, de HA0REX

All I ever see for Pi coils is cylindrically wound single layer. I remember when I built my first 6146A output cw transmitter back 40 yrs ago, I used a B&W pre made coil for the Pi.

Depending on the Q and plate resistance you see coils for multi band use up to 33 uh, in transmitters.

The only place I see pancake coils used is in Tesla coils, one of which I built with a pre made 18" tall secondary coil. I wound my own primary pancake coil.

Done right a pancake coil takes up alot less room than a cylindrically wound coil.

A six inch diameter pancake coil can have the same inductance as a three inch diameter by six inch long coil with the same size wire.

Anybody know why I shouldn't use a pancake coil in my final? I just bought a 4-1000A. from ebay.

Pancake coils are usually wound with several sections, not one large
section. The problem with these chokes is that they may exhibit
resonance within a ham band, this would be bad as the coil would
'explode' as it absorbed the power. When we had only 5 bands,
80,40,20,15 and 10 meters it was easy to design such a choke keeping any
self resonance out of the ham bands. Now that we've added 60,30,17 and
12 meters the odd's that those old chokes don't self resonate in a ham
band is not the good anymore. A single layer choke will have only one
self resonate point, and it can be made to be above 30mhz (if it falls
at 40mhz the choke would also work on 6 meters). A pancake coil may
have several self resonance points.

Sorry, they are NPN transistors. I was trying to find out what type
they may be to determin there suitability in a project. I have had
them since the early 70s. I also found another bag of them and they
are PNP. Beta measures at about 30.
Case style looks like a TO48.

Are we talking about the same thing here?
My take was that the poster was asking about the output pi network coil not
a plate choke- but I could be wrong. I took the question to be suitability
of a 2 dimensional spiral vs. a classic solenoid coil.
And for clarification, when you say pancake- are you talking about a 2
dimensional spiral?

Dale got it, Pretty clear to me he is talking about a coil 1 turn long
by X turns deep similar to an inductor etched on a PC board. Seems Ive
seen a 6m coil like this. 2 or 3 turn of copper capilary tubing.

Jimmie

Well we all know what an roller inductor is?
Here is a pix of one: http://www.palstar.com/ri20.php

So here is a link to a java program to calculate a
flat spiral pancake coil:
http://www.classictesla.com/java/calculat.html

I might have confused people with pi wound coils I'ma
not talking about pi wound coils such as the 3 pi
coil found here:
http://www.oselectronics.com/ose_p91.htm

I want to use a flat spiral wound coil to replace a roller inductor.
Like the one in the above mentioned roller inductor link.
Any pro's and con's on this topic?

I guess what I really wanted to do is make a PA
for all bands with a plug in PCB. That would have
the right size coils etched into it for each band.
So when I change bands I would just unplug one
band PCB and plug in another PCB for the band
I want. Rather than a band switch that would arc
out. Or a roller inductor that I would have to turn
to the right number of turns to get to the band I
want. Alot cheaper to plug in PCB's than the
price of a band switch with lots of wires
or roller inductor.

This would eliminate trouble switching to 10
meters with a band switch I suspect.

I'd use an edge card connector to plug the coils/PCB
into and out of an edge connector.

Well you wouldn't be changing bands with the transmitter going. So in that regard, plug-in coils, bandswitch or jumpers are about the same.

People like switches so they don't have to turn off their transmitter (to ensure not dangerous voltages) reach into their transmitter and plug in coils. If you have to reach in, at least some of the other possibilities are viable.

Your edge connector may introduce problems of bad contacts. If you have to run current through them, bad contacts will not be a good thing.

And I'd add that a large inductor may not be feasible etched on a circuit board. The only times I've seen coils etched into circuit board have been when the coils are low inductance, the sort of values you'd see at VHF and UHF. Making a coil large enough may result in way too big a plugin board.

You haven't really specified, I don't think, whether this is a tube or transistor transmitter. In the days of tubes, the transmitters were narrow band. With transistors, they've generally been broad band. So with transistor transmitters, the bandwitching has been about switching in bandpass or low pass filters for each band, and since the broadband transmitter has 50ohm output impedance, the switching is relatively easy.

> the bandwitching has been about switching in bandpass or low pass filters for each band, and since the broadband transmitter has 50ohm output impedance, the switching is relatively easy.
>
> Michael VE2BVW

Yes it's a tube PA I bought a 4-1000A from ebay there isn't much current at 6000 volts at least not for Ham Radio power. there's a variety of ways to power down the PA as soon as I start to pull the PCB out before it becomes disconnected. And to soft start it up as I'm plugging another PCB coil in.

The inductance is more dependent on the diameter of the coil and the number turns on the coil. So a 6 inch square PCB with a 6 inch diameter 10 turn coil etched on it would work 160 meter band. Or at least it has enough inductance to operate on the 160 meter band.

I've seen too many of a senior moment when they hot switch a band switch or when parasitics build up from a shorted parasitic resistor and the VHF RF goes to that band switch looking for a path to ground blowing it to kingdom come.

That sounds rather like the Norcal Sierra design.  The pluggable band
modules on the Sierra use toroidal coils for the band-specific lowpass
and bandpass filters.  The PA itself appears to be a broadband design.

Hi,

I was wondering as to how to choose the correct value of a DC blocking capacitor with least possible reactance with atleast 5V and 20mA. Center Frequency 910MHz. The value of capacitor that i need is above 200pF..

I know the thumb rule that SRF(self resonant frequency) > 2 Operating frequency. but i enquired both Farnell and Rscomponents distributors in UK as am here .., Only low value capacitors satify the above criteria of SRF. How do i proceed with the same...

Thanks a lot
Alec

I'm confused. Why do you care what the capacitance is? If you choose a capacitor that is series resonant at 910 MHz (i.e., the reactance is zero), isn't that is the best bypass capacitor or coupling capacitor that you can get.

If you are doing high volume work, you may want to standardize on a high quality (porcelain, etc) capacitor from single manufacturer so that the SRF is tightly controlled.

If you need the 200pf for DC (or low frequency) reasons, consider two different capacitors - one for low frequencies and one for high frequencies. You'll need to isolate them so they don't interact unexpectedly.

I doubt whether you'll find a 200pf cap with that SRF.

Bob.

I just got my 4-1k tube. It turned out to be a Sylvania brand.
I know Sylvania sold transmitting tubes.
But did Sylvania make them or buy them from another vender?

This one I got from ebay:
has a code date of 8806.

The history on it: was pulled from an AM
broadcast station in 1993, from the AM modulator.

And does anybody know the cold resistance or the filament?
I haven't seen any inrush current limiting circuits for the 4-1k.

Now retired I'm trying to become active again.
My TS-520S has not been on for 30 years.
I don't have a variactor (variable transformer).
At the TARC advice was to put a lightbulb in series
to take the surge.   Should I use a high resistance
(low wattage) bulb or vice versa ?
Would this be as good as a simple L-C network ?
Somebody said just plug it in. Are there any other

ideas ?
Thanks for your kind assistance.

>Now retired I'm trying to become active again.
>My TS-520S has not been on for 30 years.
>I don't have a variactor (variable transformer).

I'd strongly encourage you to ask around, find somebody who has one, and do the power-up with the variable-voltage transformer. Take your time - ease the voltage up from zerch to nominal over a period of a few minutes.

>At the TARC advice was to put a lightbulb in series
>to take the surge.   Should I use a high resistance
>(low wattage) bulb or vice versa ?

If you do this, do the former... low-wattage. You want to power up the rig *slowly*, so that the dielectrics in the electrolytic capacitors have a chance to re-form gently. The lower the wattage of the bulb (the higher the resistance) the longer it'll take to charge the power supply fully and the lower the final voltage will be.

You could do it in stages. Wire up a standard light-bulb socket in series with a power cord for the rig. Start out with a 5-watt bulb, power up, let the rig sit for a few minutes, power down again, switch to a 25-watt bulb, repeat the process again... then go to a 100-watt bulb, then a 200-watt bulb.

This approach isn't as effective, or as controllable, as using a Variac or similar variable-voltage transformer. The bulb's resistance will be low when it's cold, and will rise when it heats up... so it won't limit the initial inrush current all that effectively.

>Would this be as good as a simple L-C network ?
>Somebody said just plug it in.

It might easily go BOOM if you do. If it's been sitting around un-powered for 30 years, the dielectic oxide layer in the power supply caps may have thinned and developed pinholes... hitting it with full mains voltage and no current limiting could result in a sudden short circuit inside the caps. They're quite spectacular when they blow... messy, though.

> Are there any other
>ideas ?

Negative-temperature-coefficient resistor instead of a light bulb? These are used as inrush suppressors in switching power supplies... their initial resistance is high when they're cold, and drops when they warm up.

Borrowing the use of a Variac for half an hour is still a better way to do it, I think.

I just put my home made amper on the filament. Actually a 2.80 amp
amper.
I couldn't find my 7805 I use for a constant current source. So I had
the 5 ohm resistor in series with my 14 volt regulated supply. My 5
ohm resistor is 40 ft of cat3 3 pair telephone wire for a total of 240
ft of 24 AWG wire. I put that in series with the 4-1k filament and
across 14.0 volt regulated supply it draws 2.80 amps.
The voltage drop on the filament was 0.100 volts and a filament
resistance at 0.100 volts is 0.0357 ohms. Funny because at 7.5VAC
it's exactly 10 times that resistance.
I can't afford peter dahl transformers. I has to use MOT's for the
filament screen and plate supplies. I have to use 2 MOT's to get the
power I need. This works out to my advantage because with 2 filaments
in series it gives me 7.5VAC CT, but at a current that is only limited
by the 14AWG wire they use for the winding. Two MOT's 14AWG wire would
limit the inrush current to about 150 amps of instantaneous current at
the peak voltage.

KISS. Wire a 60w light globe in series, turn it on, let it sit for a
few hours. Filaments OFF for this test.

Havent used a variac for this for years - reason - its the switch on
current surge thats going to kill old electros, and the variac has no
current limiting whereas the light bulb does. You will see a brief
"Flash" as the caps charge up, then maybe a dull glow, eventually, no
light at all.

Given that the caps used were / are modern, and of good quality to
start with, the KISS method works well.

Oh, BTW - when all this is done, apply full mains power, let the tube
filaments  soak for a few hours lest they have gone gassy.

Andrew VK3BFA.

==============================================
Don't understand the above.
When using a variac starting at zero and gradually increasing the
voltage there can't be any appreciable inrush current.

I happen to have a 8 Amperes variac and would always use it to 'fire-up'
a previously retired oldtimer (boat anchor)

I have a rather large junk box with high capacitance value elcos  and
recently exposed them all to a 'zero to max working voltage' from an
adjustable HV PSU. I do that once every 3 years.

I went through this a few years ago with a Drake TR-4. Not having a
variactor available, someone suggested a light dimmer used for incadescent
lights. Since I was not planning to transmit nor draw much current, just
that used with receive, it worked very fine and isn't expensive. I simply
used a meter to measure the voltage. I ran several days at about 50vac and
then up to 75vac for a couple of days, and then up to full voltage.

Well, mine took out a few SMPS power supplies, and its a pain in the
arse to set up, connect meters, gingerly spend time slowly
incrementing the voltage - life is too short to stuff around......

Hey, you got time to do Rocket Science, thats fine. Each to his own.

Andrew VK3BFA.

Gosh! I thought I was the only one left making pancake coils.
Of course mine were for my little 30watt rotary spark gap TX.
Its one I use at NZVRS exhibitions to show visitors what spark
stations looked like. The "ring of fire" effect always fascinates them.
In the case of Tesla and spark gear generally the fact that the 2 ends
of the winding were widely separated was very important as the peak
voltages were so high.
It would be intersting to here if you idea pans out.

Hi Harold. I can supply your needs, but for info, I have never. in a lot of years, called on MiniCircuits Labs (MO) for a small order and not have them waive the minimum order charge if needed. VERY nice folks to work with and they make better balanced mixers than you will. They have some black magic in their ferrite department.

Have you tried Dans Small Parts?  Are hot carrier diodes
an acceptable substitute for that application?

73

Pete

Are you trying to reproduce something from a 60's handbook? I remember them speccing 1N270's but that's because those were the parts people had in the junkboxes back then. There is nothing at all magic about germanium here. The silicon diodes will require slightly more drive voltage to switch but that's not a big deal as you always drive them way into saturation anyway.

NTE109 is the ECT/NTE number for a their medium-voltage germanium replacement, officially listed in the NTE sub book, and Mouser and maybe even your local radio/TV repairman would have some. Mouser has no minimum order.

You will have much better luck using 1N914's or 1N4148's or even better a real matched DBM from Minicircuits et al. "Experimental Methods in RF Design" has a lot of good scoop on mixers that goes way beyond anything in a 60's ARRL handbook.

Hey Harold:

Try your luck with this guy:

http://www.angelfire.com/electronic2/index1/index.html

takes paypal has tonnes of them in stock and only charges

$3.95 for shipping and handling for an order like yours

The shipping cost more than the parts but there's no

minimum order.

Yes. Whats the DV/DT of the positor versus a light bulb? - I got no idea.....
The light bulb method works - its quick and dirty, and so far I have never blown an electrolytic capacitor using this method. Its also VERY useful in firing up SMPS devices - it does current limit quick enough if theres a gross fault to prevent damage.

But, each to his own. Of more concern would be corrosion /freezing of pots/switches etc. And a 30 year old mains power cable? - mm - and what about checking the insulation resistance of the power transformer..

But it ain't the Space Shuttle - live dangerously...Just Do It....

Andrew VK3BFA.

Hi all. I am looking for a 13.0 MHz crystal in an HC-49 package.
Anyone know of a vendor who might have them?

tnx es 73, Dave NM0S

The light bulb has advantages. It will light up if there is a short. You can build a rig tester by just putting an outlet in parallel with the light switch, turn it on then plug in and turn on the Rig, then turn off the switch. The light should dim and never get brighter.

Have lots of 13.000MHz in HC-50/U holders; same except 1mm pins
instead of .46mm wire leads. Want one or two?

Cheers,
Tom

That lightbulb heats up pretty quickly, especially if there is a short in the radio.

Just as a comparison:

a 250 watt bulb has a cold resistance of around 3 Ohms.

A 60 watt bulb, 18 Ohms

A 40 Watt bulb, 25 Ohms

I don't have a 25 Watt bulb handy, so I'm not sure of it's cold resistance. But the other bulbs in that neighborhood are at around 14 times the resistance hot vs cold, I'll assume it is around 60 ohms.

Sorry for the math here, but R = V squared/P

That would equal around 58 Ohms hot resistance for the 250 watt bulb

240 Ohms for the 60 watt bulb

360 Ohms for the 40 watt bulb.

830 Ohms for a 25 watt bulb

I usually use a 25 watt bulb, so discounting any inductive effects, I'll
be looking at a maximum start current of 240 watts if the radio is a
dead short, and that for only a very short period of time.

>   A light bulb in series with an inrush current limiter might be suitable
> for smoke testing equipment after prolonged disuse, though.

There isn't anything wrong with that approach, but it is probably overkill.

A couple of disclaimers first:

a) I know diddly/squat about Ham equipment. I am not a Ham.
b) I have been noodling about with vintage equipment, tube & solid-state for now over 30 years, so I am familiar with the species. What I write below is a generic approach to (re)starting vintage equipment after some years at idle.

So:

As I understand, the Kenwood is a tube-based unit, however it has a solid-state rectifier and is mostly solid-state in general. What this means is that there is some validity to bringing up the voltage slowly using a Variac as the caps will see a gradually increasing voltage - unlike what they would see from a tube rectifier which does not pass current until about 70V or so.

That it is from the transistor era, at least in part, suggests that the filter caps may be of sufficiently recent manufacture as to be likely to be good - the operative word here is *LIKELY*, not *certainly*. Kenwood was also not know to use cheap-junk caps in their equipment.

HOWEVER: A variac is really no better than a dim-bulb tester unless it is equipped with a current meter (amps or watts) that will read the actual current draw of the unit. I have been known to RANT on this subject at length - but I will spare this group and merely state that UNLESS you have the means to measure actual current drawn by the unit and at a sufficiently fine degree as to give you useful data, don't waste your time with a Variac. It gives you a false sense of security.

IF you have the means to measure current - either with your VOM in series or with a poor-man's ammeter (measure voltage drop across a 1-ohm resistor, for example), this technique is very useful. Raise the voltage s-l-o-w-l-y, watching the meter all the time. It will jump up (typically) then slide down as the caps charge. Slowly-slowly-nicely-nicely until you reach operating voltage over 4-5 minutes or so. And KEEP WATCHING!

If the caps start to fail at full B+, you will see that meter creep up. If they go anything beyond about 80% (SWAG guess - more below) of the nameplate rating of the unit, you have real problems.

Now, here is where I cannot comment beyond the generic - I have no idea what the quiescent vs. active current draw is with the Kenwood. THIS IS IMPORTANT. As you will not be transmitting or whatever, you should be operating at/near the quiescent current. This may be a very small percentage of the full nameplate rating - my guess is that this is so. You will need to know what that is. If you are operating even 5% beyond the "proper" quiescent current, that will be expressed as heat somewhere - and eventually *POOF* at some unobtanium or expensive part.

You get the point. The idea is to bring power to the beast slowly so that failed caps or similar may be discovered before any actual damage is done. For this to work you need a means to determine whether the unit is taking excess current - and you need to be able to measure this in fine-enough increments to be worthwhile. Otherwise, you are wasting your time as a small problem or series of small problems will be invisible to crude means.

I keep this unit for these sorts of tests:

http://www.oaktreeent.com/web_photos/test_gear/Heathkit_IP-5220_web.jpg

It is an metered Iso-Variac, overkill for once-in-a-while needs, but I use it constantly.

Peter Wieck

>
> If the caps start to fail at full B+, you will see that meter creep up. If they go anything beyond about 80% (SWAG guess - more below) of the nameplate rating of the unit, you have real problems.
>
> Now, here is where I cannot comment beyond the generic - I have no idea what the quiescent vs. active current draw is with the Kenwood. THIS IS IMPORTANT. As you will not be transmitting or whatever, you should be operating at/near the quiescent current. This may be a very small percentage of the full nameplate rating - my guess is that this is so. You will need to know what that is. If you are operating even 5% beyond the "proper" quiescent current, that will be expressed as heat somewhere - and eventually *POOF* at some unobtanium or expensive part.
>
> You get the point. The idea is to bring power to the beast slowly so that failed caps or similar may be discovered before any actual damage is done. For this to work you need a means to determine whether the unit is taking excess current - and you need to be able to measure this in fine-enough increments to be worthwhile. Otherwise, you are wasting your time as a small problem or series of small problems will be invisible to crude means.

Peter - lots of good stuff in there, but perhaps overkill..like the ac power supply with its own meters - would be simple to use for the methods you describe.

The Kenwood is a "Valve hybrid" - there are 3 tubes in there, a driver and 2 output tubes in //. Filamnets are switchable on/off. Idle current is.....very low, never measured it, had no need to. The light bulb method does work sufficiently well for the purpose intended.

I think I missed just what type of rig it was. If it a Kenwood TS-830, the owner has to immediately ship it to me, as those units had a particular problem that ony I can fix.

I tested out one of those, and fell in love with it. Good sound, Hot receiver, good looking rig, The big issue with those was the band changing switch. Not a big deal.

Heck, I'll even pay shipping ;^)

I think that turning it on, blowing up the capacitors that are gonna blow up, and then replacing the ones that actually did blow up is a fine procedure, myself.

There is a certain pussyfoot attitude about either cranking up the variac gingerly, or simply recapping the whole radio, that is not really appropriate to somebody (me!) who really wants to see smoke coming out at least once in a while.

Only gotcha, if the bad capacitor takes out a transformer, that's a PITA. Not that I've never rewound bad transformers or rewound them for a project, but having to rewind a transformer just because I was impatient is a little embarassing.

Tim.

It seems almost criminal that GNURadio / USRP isn't mentioned. :-(It's the main ham radio SDR that's being used for VHF/UHF work with correspondingly higher bandwidths. (Whereas HPSDR/Flex-5000/etc. are aimed more at super-weak signals -- more dynamic range -- with correspondingly narrower bandwidths.)

Problem is I need a small handful to fine trim the drift on
a set of HBR receiver LO coils. I refuse to pay those prices
for what should be 25 cent parts. Yeah, I know, price of
doing business, only game in town... etc... But, there must
be some lanquishing in junkbox looking for a good home
for a fair price. I'd hate to blow 20 bucks on a bunch of
cheap parts that I may or may not need.

I suspect N750 ceramic discs would work just as well in this
application, and I'll try them if I have too. At least they
are cheap and available.

Pete

 I think you going to has to jump the fuse to get away with that?
Nothing I hate more than shorted parts especially a shorted fuse.

...snip...
sounds good

Just to add. In the days when boat anchor stuff was the normal gear, when items had been on the shelf in storage for long periods, the electrolytics were not so good then as now :)

Switch on procedure from storage was:

1. Expect the odd "phut and horrible smell." It *will* happen at some time.

2. Switch on for a few seconds and then off - allows the electrolytic barrier in the capacitor to start to re-form - the number of seconds for certain equipment was specified - otherwise about 5 seconds for the first time.

3. Switch off for about 60 minutes.

4. Switch on for 10 secs and then off for 30 mins.

5 Switch on for 30 secs and then off for 30 mins.

6. On for 30 sec off for 10 mins.

7. On for 60 sec off for 5 mins.

8. And so on....

These were valuable equipments and the manufacturer normally laid down a procedure. The whole idea being to re-form the electrolytic capacitors and to give other problems time to cool down for inspection and detection/rectification.

The alternative was just to switch on and then stand back from the bench with your fingers in your ears and a handkerchief over your nose :D

And so, like all good "tinny and bullshit" sessions, we come back to the original question - if Dave hasn't wandered off, in boredom or disgust. And like all good amateur arguments, we have suggestions ranging from ludicrous to....ludicrous.

We have had - an engineered, high tech solution
A stuff it, just power it up solution
The KISS solution - use a light bulb in series
The do it slowly and painstakingly with a metered variac solution
Some reminiscences about the "old days"
Someone else offered to buy the radio, but got their models mixed up.
Answers from people who, well, really....dunno why....

And all valid, all correct - so, Dave - take your pick which one YOU use.......alternatively, there is a TS520/530/820/830 group on Yahoo. You could post your question there - they have heaps of people who lovingly use, restore these old radios - mind you, the answers will be as broad spectrum as here, and LOTS more off em hi hi.

Andrew VK3BFA.

So after all that, any hints on what the original project was? Even
in the 1970s people were speccing matched silicon diodes (e.g. 1N914)
or hot carrier diodes (e.g. 5082-2800) for mixers.

I almost forgot this thing draws more filament current at a lower
voltage
25 amps at 7.3 volts DC

Not really, but a former schoolmate has worked at a place titled
"Center for Non-Destructive Testing" and my first comment to him (like
15 years ago) was "Where's the fun in that?"

> > Only gotcha, if the bad capacitor takes out a transformer, that's a

The fuse is there to help (not guarantee) stop things from catching on
fire and burning down your house.

It's not there to save components.

It is sized based on primary current, not the current capacity of any
individual secondary or the components hooked to any individual
secondary.

At least two volumes of "Single Side Band for the Radio Amateur" and
many ARRL handbooks from the 60's show 1N270's used in balanced
mixers.

It was a jellybean of the time, it's odd that someone would not
realize it and slavishly want to use it rather than something more
readily available (and performance-wise far superior) today. Probably
the same guys who insist on carbon-composition resistors everywhere
today too :-).

There are some things that appear in old construction articles that
are worth finding. For example, the BC-453/454/455's tuning capacitors
and drive mechanism are truly superb and I still keep my eyes open for
them today :-).

Tim.

Filaments like lamps are not ohmic, but I don't think they should ever draw more current at lower voltage. That would mean "negative dynamic resistance".

Seems more likely there's some measurement difficulties. Getting good contact on the filament pins through thermal cycles is often an issue.

For the money, and if you can get to Kutztown, I will have a
consignment of SSTRAN AMT3000 units. $80, including all taxes and with
the SMT chip already installed.

www.sstran.com   for additional information.

Phil is a neighbor and give a very good price for the show as a
courtesy to the DVHRC. We choose not to mark them up as a courtesy to
attendees.

We recently moved into a 4200 s.f. house (grandkids and all that), the
transmitter more than covers it and gets our nearest neighbors and
then some with just the kit-supplied wire antenna.

Do a search on this NG, you will get all sorts of additional
information on this and many other transmitters.

Peter Wieck

In case you don't get any bites on anything more to your liking, Ramsey has a
kit at
http://www.ramseyelectronics.com/cgi-bin/commerce.exe?preadd=action&key=AM25.
I have one, and have used it for the past 3 years with no problems.  The only
thing I can suggest if you settle for this unit is to scrap the supplied wall
wart and get a regulated, filtered 12-15V power supply.  It solves a problem
with hum and distortion that the supplied power supply causes.  Ramsey has known
about this problem for a long time...  don't know if they still ship the kit
with the bad PSU.
Download the manual from their site to get an idea of the complexity of the kit.

Cheers!!!!

Indeed. I have several old ARRL and RSGB Handbooks and a number of older references (including Single Sideband for the Radio Amateur).

You can see the fashions change. At one time the cool part to use was the 7360 beam deflection mixer tube; at other times the challenge was to see how many 40673 MOSFETs you could use in a single radio. Many of these designs are difficult to reproduce now.

I'll see your BC-455 tuning capacitor and raise you an Eddystone dial. :-)

You can make nice radios by applying the right technology to the problem. My recipe for a stable VFO nowadays is a postage-stamp size surface mount board mummified in bubble wrap and stuck to the end of a good, solid air variable capacitor.

What's amazing is that some of the SSB rigs appearing in the 60's in
the pages of QST use not one, not two, but three 7360's :-).

40673's were also used with wild abandon. If someone wants an honest-
to-goodness 40673 they can pay $15 for a NTE221 in a metal can, but
most experimenters would use a BF998, obviously a different package
but same function.

The brass-screw-in-a-solenoid is something I just tried in my
reproduction of the MMR-40 and I am very impressed with its stability
and mechanical simplicity as a PTO. A similar but not identical
mechanical design is used in the WA6OTP PTO, I haven't tried it yet.

Tim.

Though not actually PTO if it's a brass screw, right?

Cheers,
Tom

Permeability of brass is slightly less than air, which is why the PTO goes up in frequency as I screw the brass screw in.

It's not an iron-powder slug (which would go down in frequency as it enters the solenoid) but it's still a PTO.

If you haven't tried them, I highly encourage you look at the PTO in the MMR-40 and the WA6OTP PTO. Completely 100% homebrewable and I'm very happy with the results.

Tim.

Peter,

That transmitter is NOT FCC part 15 compliant for what I know.

This would be misleading as the OP requests a part 15 transmitter
BCB.

Syl

I believe it meets the FCC regs regarding "homemade" Part
15 devices; and would be limited to the maximum number
of units allowed per individual--five, if I recall correctly.

Pete

Dear Senor Pedro,

That "part" is unclear to me. I try to understand what makes
a transmitter Part 15 compliant when homemade as opposed
to a commercial unit. Does the 100mw input still holds
(but owner/builder doesn't have to get "approved" by FCC) or
is it a don't get caught transmitting on a commercial
frequency -i.e. create interferences- and you'll do fine thing ?

Syl

=46rom the website:

=B7 Legal to use in the US, no FCC license required

=B7 Fully compliant with FCC Part 15 regulations

=B7 100 mW input power

=B7 100% Modulation

=B7 20Hz to 20kHz =B11 dB Audio Response

=B7 Very Low Distortion

=B7 Adjustable Audio Compressor/Limiter

=B7 10 kHz and 9 kHz channel spacing options

=B7 High Quality PC Board and Components

=B7 Comprehensive Instruction Manual

This is a "HOME MADE" unit - which means that it must meet maximum
power radiation requirements, antenna developed length requirements
and various other regulations. EXACTLY the same as the Ramsey kit, the
AES kit, the L'il 7 Kit and any of several others.

What it is NOT is approved to be sold as a full-built unit.

Makes it Part 15 - compliant.

But, by removing the spaces, you can get chapter-and-verse from Phil Bolyn at info at sstran dot com.

I would have to check the CFR to be sure, but IIRC building a homemade Part 15 compliant transmitter doesn't absolve you from the basic requirements for operation in the MW broadcast band like keeping the DC input power to the final below 100 mW and the length of the antenna/ground system to 3 meters or less, I think homemade status only eliminates the need to do the more complex certification tests necessary for commercial units.

I also suspect that if you are using a Part 15 transmitter, either homemade or commercial, and it interferes with a commercial frequency, then it is your responsibility to resolve the interference problem, or shut the transmitter down, I don't think commercial units get any special privileges in this regard, although again I would have to check the CFR to be sure.

```

This is a misleading statement, the SSTRAN AMT3000 does not include a limiter, manufacturers claims not withstanding. A traditional limiter as used with AM transmitters controls the modulation peaks, either by a clipping operation, or with a high speed peak activated AGC amplifier, the SSTRAN AMT3000 includes neither of these circuits. The so called "Compressor/Limiter" used in the SSTRAN AMT3000 is an RMS controlled AGC amplifier with a knee in its compression curve. The RMS control means that it doesn't pay any attention to the peak levels that cause over modulation. SSTRAN calls it a "Limiter" because of the knee in the compression curve, but it fails to operate as expected of a limiter to prevent over modulation.

Mon Ami

I tried googling the FCC website, but not much luck...
There is (was) a section that mentioned that it was legal to build
a part 15 transmitter, provided it meet the FCC requirements for
regarding power, antenna limitations and spectral purity. There
was a limit on the number of such devices that could be built and
owned by individual as well.

Hi Peter,

Thanks. Several of those specs do bring questions though as they aren't properly defined (unless they are in the full FCC documentation ?

i.e.

a) Just what "very low distortion" means ? To me, very low distortion would be 0,001% as a minimum. But I understand that in the real world of transmitters, 0,1% is probably considered very low distortion figures ? This based on the presumption that attaining 0,001% distortion figures is easier to attain than using tube technology. Correct me if I am wrong.

b) Adjustable compressor/limiter. To what levels ?

c) High Quality PC Board and Components. Does this means the homebrewer can't use Chinese made parts [grin]

Of course I do not mean to start a discussion on these points,
merely thinking out loud...;o)

But...I now better understand the requirements for part 15. As It shows, the only difference between a commercial unit and a homebrewer's is the latter does not have to pay labs testing and approval for his "concoction" whereas the former (the manufacturer) has to have the FCC seal of approval and the of course the onerous fee(s) along with the approval tag.

I wonder how the FCC manages the homebrewer's "concoctions", other than reacting to complaint(s) ? I suspect this is what happened to the kit builder whom got fined sometime ago ?

Syl

They basically respond to complaints, as I recall. It's a common-sense sort of rule. You can transmit at a power level that covers your house, or your yard at best. You can't go above that level without possibly interfering with your neighbors' reception. Duh. I'm not interested in building a pirate radio station, so I can't imagine why I'd want a transmitter that could broadcast beyond our house.

I dimly recall discussions about that kit builder, but it seems he was selling manufactured units as "kits," or possibly selling non-compliant manufactured units without going through the certification process.

If you're simply piddling around in the basement and trying to build a house-level transmitter, there is no certification process. Just don't interfere with reception in your neighbors' houses, lest they complain.

Common sense rules :-)

Phil Nelson

The 465's specs were DC to 100MHz.

- the '465 is ok for a rough testing, but you may have turned the IG-42
output level way down?

Remember, the signal level output level can be adjusted from a max of 100
millivolts down to the microvolts level - and your 'scope will not show much
if the signal level is belov approx. a few millivolts.

So, crank up the level to the max of 100 millivolts and do the measurements.

Does this help?

The only scope calibrators I've seen have been a jack or something on the
front panel of the scope, so when you touch the probe to it, you take
into consideration the scope probe, the cable to the scope and the input
circuitry.  The "scope calibrator" is as useful for a quick check like
this as an potential calibrating use.

And as someone pointed out when he asked elsewhere, a digitally tuned
radio will be useful.  Even an analog, since you can at least tell if
the generator is putting out a signal by tuning the radio and the
generator to the same frequency, and adjusting one slightly if there's
no output (to ensure one isn't off-frequency).  A shortwave radio has
the advantage over the average table radio since it can tune higher in
frequency.  When I had an SP-600, it was about the best piece of test
equipment I had.

Well you should see the signal fine on a 100MHz 465.
I have a very similar generator and I was just using it today to set up
some filters with no problems at ~7.8 Mhz, using a 60Mhz Telequipment scope.
Does that model Heath sig Gen have an output meter? Make sure the coarse
attenuator switch and fine level adjustments are fully clockwise. You
should get more than full scale on the meter when switched to Rf level.
If thats Ok then you should get around 100mV or more at the scope input.
Are you perhaps using a /100 probe, there are a few around. Most scope
probes are x1 or /10 switched though.
If the scope is indeed working and your trigger is set to auto with the
Y input at ~50Mv/div you should get plenty of signal at all of the
generators frequency range. If no display then you may have trigger
problems at higher freqencies with the scope.

Any Tektronix scope from 541 on up to 465 or 475 is good enough.

I have a dusty IG-42 in the workshop (replaced by an HP606).  It still
works fine and remains in power output calibration although the
frequency markings were never that good.

I almost hate to ask, but did you check the tubes inside your IG-42?
At least to see if the filaments are glowing?  A couple of sheet metal
screws in the back hold the main case shell to the main assembly.

BAMA doesn't have a manual on the IG-42, just the SG-8 (the model
without the output meter or better attenuator).  I have
one...somewhere
in the old stuff in the workshop.  I could scan it if I can find
it...and the
nice Kodak all-in-one is working (which it isn't as of a few days
ago).

This portable antenna can be used for the top section of a Vertical Antenna OR Horizontal elements for an Antenna System such as the Buddipole tm ...... A Great QRP / Portable Antenna weighs only 400 Grams [14 Oz] and measures 104" extended yet only 14" long when folded. Picture
The construction is the same as is used for sectional fishing poles. Each of the 8 hollow tubular metal sections has a plug one one end and a socket on the other end. All the sections are connected by a string made of either a cloth or metal cord. At the bottom of the base element there's a spring inside the tube to tension the cord. Some units may use an elastic shock-cord material. This way all the elements are kept in order when they are disconnected from each other and are held together when assembled into a 104" [8.6 Ft] long antenna. When the elements are folded or disassembled the package is only 14 inches long.
The base has a male 3/8-24 thread which is the same as is used on most Ham Radio and CB antennas. Some sort of spring base could be used when this antenna is used because the hollow antenna elements will "fold" if too much force is applied to them.
These units are in Like New Condition.. Sold AS-IS but will not be DOA.

I'm finding that if you're looking for any heatsink that there are zillions of places to pick one up and that if you are looking for a particular sink that it is a futile task. With a little help from my friends, I'm putting together the mosfet amp in the 2006 handbook and I've pretty much secured everything on the parts list save the heatsink. It is the same unit that was used on the original FARA amp as well. Anyone have this beast in the junk bin or know of a purveyor who might?? I've scoured the web and no joy so far. The sink is an AAVID part (#244609B02). Thanks in advance all.

Apart from some teflon wire (thanks again Pete), Mouser had most of what
I needed.  Unfortunately, they no longer carry said heatsink.  Thanks
though.  Other ideas ??

Gary

start here:

http://www.mouser.com/Search/Refine.aspx?
FS=TRUE&Ntx=mode%2bmatchall&Ntk=Mouser_Wildcards&OriginalKeyword=aavid+&Ns=P_SFiel
d&Ntt=*aavid*&N=1323038&No=0

if you know the parameters of the heat sink in question, a search through
these pages on the Mouser website should give you what you need. there are
several pages to go through, so you do have your work cut out for you!

Pete

Thanks for the advice. Mouser very nearly had a replacement. The unit
has horizontal fins instead of vertical and as my application is
convection-only, this likely tips the balance on effectiveness (safety).
Did find another site and it looks like a good one. It's Nebraska Sales
and Surplus. I've purchased from them before and have no complaints.
Thanks again for the quick replies.

Gary

===================================
For large heatsinks (perhaps not precisely the type you need) flea
markets will be a likely source . Otherwise there might be an
electronics surplus store in your area .
Some time ago someone gave me a clapped-out (probably illegal) CB
amplifier (of Italian origin) with a heat sink to suit your project
........however I am in Scotland- UK ,otherwise I would be happy to
send it to you .

Thanks for the thoughts Frank.  I would not have guessed this before the
fact but I'm finding that tracking down / scrounging these bits and
pieces is actually fun (I am also sure that there is great probability
that I will rue these words...).  Thanks again all.

Gary

Aavid makes so many heat sinks that you almost have to buy custom to get
what you need.

Usually your best bet with heatsinks for a one-off is to find one that
meets your needs and use it, even if it's not identically the same thing
as the plans.

If you can find one with specifications get one that matches the thermal
conductivity to the air as what you have; if you can't get one with
specifications look for about the same or greater total surface area and
fin spacing.

The handbook used to have directions on bending heatsinks from sheet --
you basically make a bunch of nested 'U's with heat sink compound
between. I don't know how well that works, or if they still do it. I

suspect that for natural convection you'll be fine with that.

Don't worry about finding the exact, go the next bigger heatsink! You
will not be sorry you did.

While you are at it, consider mounting a muffin fan on the sink to push
air though the ribs (if the plans don't already call for one.) Again,
you won't be sorry you did!

I have not seen the plans you are speaking of, but I am taking it for
granted it is a leen-e-air.

Regards,
JS

I don't have a copy or the 2006 handbook, so I can't visualize the heatsink that
you're looking for.  Low resistance heatsinks are usually made from extrusions
and can be any of a number of designs.
Is there a photo in the article that shows the heatsink?  Possible for you to
```

post a scan of it on alt.binaries.schematics.electronic? Also, the dimensions of the heatsink would help to find a substitute and source.
If you're in or near the central Florida area, Skycraft usually has a couple bins of heavy heatsinks that might suit the job. I bought a couple that calculates to about 0.5 degC/watt each about a year ago. Last time I was in the store (in February this year), they still had about 10 of them on the shelf.

You mentioned that it was also used on the FARA amp. Is there a link to a web page that describes (hopefully with a photo) the amp?

Cheers!!

Oh, that's ok Gary. I hope you find the one you are looking for. Most of
that stuff from Surplus Sales of Nebraska came from the Inventory Disposal
sale from Rockwell-Collins, which means that it is of good quality.

Pete

I've found several good heatsinks and power supplies at Goodwill. I
purchased an old stereo amp that had 6 100 watt channels. The last one
I bought cost less than $20. I am really surprised at the way people
cast things like this off. It is now the heart of my home
entertainment system.

Jimmie

\

Don't forget old land mobile radios like MASTR II, Mitrek or SyntorX for
some heat sinks with great thermal mass. You may need some metalworking
tools to cut off and smooth down the mating area neded for your device
layout.

OK, I found a copy of the article that you're building. If it's the same
article that's in the 2007 handbook (titled "A Broadband HF Amplifier Using
Low-cost MOSFETs" bu WA2EBY), then maybe I can help with the heatsink.
I found a photo in the article that shows pretty clearly the heatsink as mounted
on the rear of the chassis. I'm guessing at the dimensions of the rear panel of
the chassis. The box is given as 3.5x6x8, but it's hard to conclude whether the
rear panel is 3.5x6 or 3.5x8.
I assumed the rear panel to be 3.5x8, did a bit of extrapolation and estimated
the size of the heatsink to be approximately 5.5" wide, 2.75" tall, 1.25" fin
height.
Newark shows a heatsink meeting those measurements (approximately) at
http://www.newark.com/54M0782/fans-heat-sinks-thermal-management/product.us0?
sku=fischer-elektronik-sk-85-75-sa,
and appears to be in stock. The given measurements for that heatsink are 160mm
wide, 75mm tall and 40mm fin height, with a thermal resistance of 1.2 degC/watt.
No clear area in the middle, so you'll likely have to drill & tap the base to
mount the transistors.

The heatsink itself is reasonable enough, but the caveat is that it's stocked in
the UK and drop shipped from there, with a $20 handling fee.

I stopped searching when I found that heatsink, so you might do a more thorough
search using those approximate measurements and find something suitable, and
less expensive.

Cheers!!!

That's the one that's sort of a clone of the S-38?

There's the classic modification article in "73" about 1964, where
someone trading it in has to undo all the modifications, and just

as he gets to the store he remembers one last thing he hadn't undone.

There was an Indian ham who wrote quite a few articles in the late sixties and early seventies, and he had an article in QST about 1971 or '72 which I thought was about the S-38. That particular article was about his odd method of receiving CW, go for a really low tone (and he explained why, I can't remember the details), but he talked about the troubles he had with stability. I think he solved it with a crystal controlled converter (I think he had two articles about that one, a 7360 based converter that was like the front end in a QST receiver, complete with front end Q-multiplier, and then a mosfet version of the same basic design).

You should be reading Popular Communication this month. Some guy is writing about his first Lafayette receiver.

But seriously, when I saw that, it reminded me not of having that early receiver, but of finding an entry in home hanyman's encyclopedia for that first Lafayette receiver of yours. I guess it was put out by Mechanix Illustrated, and had some articles from Electronics Illustrated. Not that much, but when I was 10 or 11 and looking for electronic and radio things to read, finding the few in there was great. Unfortunately, I can't find the specific volume, that I did look for after noticing your column in the magazine.

You might look into a "huff 'n puff" stabilization scheme. The link
below is a good place to start:

   http://www.hanssummers.com/radio/huffpuff/index.htm

Good luck!

Thought of one, but the drift rate is too fast for many
H&P circuits, plus it would exceed the lock range
in short order...

It is the clone of the HE-10, which looks like the S-38 :)

I added a voltage regulator, which stopped the oscillator
pulling problems when running the IF gain up and down
(thirty volt swing!). I did a few other simple mods to
get rid of residual hum in the headphones (ground loop
on filament grounding and added one more filter stage
in the PS.) But this drift has me stumped. I tried a
few different osc. circuits, but the design is weird.
It is basically a BS Hartley, except on the highest band
which requires a feedback loop back to the plate to
get it into osc. I suspect it is the nature of the beast.

I had a Hallicrafters S-120A, which was transistorized, the
only shortwave receiver that I could afford in 1971, and it
has to be the worst receiver ever sold.  Not just the usual
faults of bad dial, bad image rejection and bad stability, but
it had the bonus of overloading really badly because they weren't
designing good solid state receivers at the time.

We lived with them because we couldn't afford anything better.
I'd say the experience of having such a bad receiver often
included attempts to improve them, even though they started
out so bad that it was impossible to do much.
```

The transistorized one, at least when I was 11, was too undecipherable to do anything to. I did really get a handle on SSB, since while the receiver had a BFO, it wasn't strong enough to demodulate SSB. I kept having the feeling that the receiver was overloaded, that's what the SSB sounded like, and I think without prompting (but I can't remember for sure) I got the idea that if I attenuated the incoming signals I could demodulate the SSB. So I took pot scrounged out of something and used it as an attenuator between the antenna and the receiver, and I really could demodulate SSB. The problem was that I had to attenuate the signals so much that only the strongest could be received. Of course, turning down the RF gain was basically what they told you to do to receive SSB on pre-SSB receivers, so either I discovered the idea by myself, or did read about it and put it to use, I can't remember which.

I remember looking in the Handbook at the a filter to keep broadcast radio out of the receiver, and pricing the toroids placed the project out of my means. It might not have helped anyway, since the receiver wasn't really shielded, and it seemed to overload from all the broadcast signals, AM, FM and TV, while the filter was only a high pass filter if I remember properly for AM broadcast.

I went from that to a Hammarlund SP-600, you can hardly make a bigger jump.

    Michael VE2BVW

I have a few SOLA brick type power supplies that were given to me. I am looking for schematics so I can repair them. On some the problems were pretty obvious. Bad filter caps, rectifiers pass transistors. These were easy to repair. I suspect they are all type 723 regulator based but I am not absolutely sure as one power supply has an IC that is clearly an op-amp, this does not appear to be an origonal chip. Other power supplies have parts missing. Any help would be greatly appreciated.

Jimmie.

DF4ZS developed a RF speech clipper that fits into the Yaesu MH-31 microphone shell. This mic is used with the popular, tiny FT-817 transceiver along with others and in all speech modes. His clipper has a SSB IF.

Details: http://jwm.de/afu/0ft817eng.htm
Reviews: http://www.eham.net/reviews/detail/2732 (6)

There are no reviews of the VoiceMax on eham.net while there are 21 of the W4RT Electronics "One Big Punch" which uses a similar IC and can be installed either in the MH-31 or inside the case of the FT-817 et al.

DF4ZS also makes an outboard RF Clipper with adjustable a.f. compression and integrated noise gate.

If you don't mind tying up a computer to do your speech processing, VE3NEA developed freeware to work with a soundcard between the mic and the transmitter that functions as bandpass filter, 7-band equalizer, noise gate, compressor, and RF envelope clipper. http://www.dxatlas.com/VSh=
aper/

This DF4ZS is a clipping type processor... nothing like the VoiceMax
audio compressor. You are correct, Since VoiceMax is a new product and
there are only about 150 units in use worldwide... so far there are no
reviews on Eham. Thanks for your interesting comments.

That is true. SSB RF clipping is proven to deliver an honest 6 dB
improvement.

<DESCRIPTION> Comments on WT 98-143
<NOTIFY> erlpnk...@aol.com
<TEXT>

To the Members of the Commission Assembled:

I am Steven Robeson. I have been a licensee in the Amateur Radio Service since 1972 and am presently the licensee of Amateur Radio Station K4YZ and hold an Amateur Extra Class Operators license. I comment to you today on the matter of WT 98-143.

There can be no doubt that there has been quantum leaps in the field of radiocommunication since the last major rewrite of Part 97. This includes the "Incentive Licensing" system that was implemented in the late 1960's. It is clearly time to change the system.

The Commission has solicited comments relative to that circumstance, and I hope the following will be considered in that act.

First of all, I would like to wholeheartedly approve of the concept of reducing the number of Amateur License classes from six to four. There is much confusion as to "who's who" as it is now, and a reduction in the licensing process would alleviate that disparity. As such, I envision the following as being appropriate for said restructuring:

Amateur Class D: The Amateur Class D license would become the de facto "entry class" license for the Amateur Service. In light of the grossly decreased demand for the Novice License and reduced useage of the sub-bands allocated for thier use, I would deactivate it as the "entry class" licenese. The Class D License would for all intents and purposes be the same as the current "Codeless Technician" class license. The examination for this license would remove questions pertaining to HF (1.8 to 30 MHZ) theory and operation, and be strictly limited to matters pertaining to VHF/UHF theory and operation, regulatory matters and Amateur practice. All Amateur privileges above 30 MHZ would be conveyed to the successful applicant.

Amateur Class C: The Class C license would be the entry level license for operation on the HF spectrum. It would require the successful applicant either hold a Class D license, or successfully complete the Class D examination in addition to an examination on basic HF theory, propagation and practice. It would also require an examination in proficiency in the sending and receiving of Morse Code at a speed of not more than 5 (five) words per minute. Persons presently holding a Novice Class License or Technician Plus license would be grandfathered into this class of license, except that they would be required to take a 20 question open book examination at a VE Testing Session on the privileges and restrictions of the Class C License prior to utilizing those privileges. Allocations would include those presently enjoyed by the Amateur General Class licensee except for operation of the 160, 30, 17 and 12 meter bands.

Class B: The Class B license would incorporate the present Amateur General and Amateur Advanced license. All amateur priviledges as are presently enjoyed by the Amateur Advanced would be authorized with Amateur General's being grandfathered into Class B. New licensee's would be required to pass a written examination on advanced radio frequency technology, amateur practice, regulations and an examination in proficiency in the sending and receiving of Morse Code at a rate of not more than 12 (twelve) words per minute. This would be consistent with the present CEPT program, which the United States is presently negotiating membership in. Additional frequency allocations would be authorized by the "refarming" of the subbands presently allocated to the Novice Class, and divided with the Class A license.

Class A: The Amateur Class A would convey all Amateur operating privileges to the successfull applicant. Present subband authorizations enjoyed in the "CW" bands would be unchanged and new exclusive phone allocations for the Class A would be "refarmed" from the deactivated Novice license and by rellocating from the "high" end of present CW allocations where operation is sparse. A quick scanning of those portions of the spectrum will demonstrate that minimal use is made of this portion of the authorized allocations and reallocation to "phone" or other "wideband" emission types is reasonable.

The Class A applicant will demonstrate advance/expert level knowledge of RF technology and Amateur practice. No additional Morse Code examination would be required.

To further simplify the administrative process of the Commission, I would discontinue the present "sequential" callsign system. Upon successful passing of the requirements for an Amateur Examination, the applicant would be issued a "2 by 3" callsign (ie: KA4AAA) by the Commission. Those wishing to specifically select a callsign of a particular format would be provided that opportunity by the "Vanity" callsign system. The Commission would specify those formats of callsigns permitted by class, but it would be up to the applicant to chose the desired call, and appropriate fee paid for the privilege of obtaining said call.

As for the occassionally emotional debate on the retention of the Morse Code requirement, I am steadfastly in favor of retention of the use of Morse Code and demonstration of it's use for the Amateur Service. Among it's prouder traditions has been the Amateur's ability to communicate across international boarders and foster communication between citizens in countries which may not have a common language in which to conduct that communication. Morse Code is the "common denominator" in international communications and should be retained.

As for the arguement that more efficient or reliable methods of communication exist, it is a time proven fact that the simplicity of Morse Code systems has allowed us to communicate with portions of the world that cannot enjoy the same level of access to technology that we as American's enjoy.

And to echo the comments of another commentor to these proceedings, I would like to express my concern over the decline of the overall technical skill and knowledge of the average Amateur. I firmly believe that this is the direct result of the publishing of Amateur Radio question and answer test pools in the public domain. I feel it is as rediculous a concept as for our schools to prepublish the questions and answers of mid-terms and finals. Closing the pools except to the VEC's, the Commission, and an independent oversight committee approved by the Commission would go a long way towards ensuring that the successful applicant has a minimal and sufficient retention of the requisite knowledge for an Amateur license.

Lastly, I would consider all of this for naught if the Commission were to fail to make a determined and on-going effort to enforce the rules and regulations as they pertain to the operation of Amatuer Radio Stations. It is an embarrasment that we are as frail as any other subset of human society, and we too have our share of ner'-do-wells and rabble-rousers. But unlike a local "protest" or civil disturbances in one localized area, radiocommunication has the potential of causing a disruption over a massive, if not world-wide area, even when that disruption is perpetrated by only a few "rotten apples". The Amateur Service still prides itself on it's own "self policing" activities, and this activity is unprecedented in any other Service under the Commission's domain, but only so much can be accomplished short of vigilanteism. The Commission's assurance that they will enforce these regulations and back it up with action will be the one greatest action the Commission could take.

Respectfully Submitted,

/s/ Steven James Robeson, LPN
Amateur Radio Staton K4YZ

Has anyone tried a 6JH8 in place of a 7360 for the
first mixer in a homebrew RX? How did they compare?

Pete

Whoops.

All I know about geography is that the civilized world ends at the
Mississippi river.

Which is what they think in New York, too, but those crazy folks think
that _they're_ in the civilized world!

```

Our local repeater has just started to use CTCSS and my poor old 2m
Rig has no CTCSS.
Has anyone got a simple circuit for this, also i think i will need a
circuit diargam for the radio. It is an old FDK Multi7, crystal rig.

Any help or suggestions would be great!

Andre

Personally I use a cheap FET,100 amps is like $3.00. With 0.004 ohms on resistance. Dual 30 amp schottky diodes for a 60 amp bridge. A TL431 as under voltage detector to clamp the gate to ground for short circuit protection. I gain a few extra volts because of the diode drop is lower and low on resistance of the FET. Which translates into more current from the same supply, that used bipolar transistors and regular diode bridge.

The one I had used triple conversion superhet. Mircoprocessor
controlled.
The first IF was like 336Mhz to 10.7Mhz to 455Khz. There was no front
end. just direct conversion to the IF. So all the micro had to do was
control the oscillator from 336Mhz to 900Mhz using up conversion on
the low bands and down conversion on the higher bands. Cell phone band
was locked out. Guess what you can pick cell phone band on the image
frequency back in the day.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

Thanks for your comment. In regard to your email... more VoiceMax
modules will be available earlier than expected... around August 1st.
We should have a few left after the back-orders are sent out.

Given how much time was spent discussing the need for image rejection and the sometimes-elaborate techniques for achieving it, I suspect a lot of my college professors would be incredulous to learn that many receivers do just fine without it.

I've noticed that many Yaesu radios lock out the images of the old AMPS band, which sucks because the image is where there are also 100%-legal-to-receive paging bands. Yaesu lost a sale to Icom over this.

Hopefully the stupid law will be dropped one of these days -- it's not like any large percentage of all cell phone conversations are carried out on an AMPS anymore, and most of the cell phone carriers are quietly shutting down their old AMPS equipment altogether.

Are analog cellphones still used in the USA ?
I thought by now it is all digital sigs which can not be received with a
'normal' receiver , so what's the reason to 'lock out' the cellphone
frequencies ?

The same government logic that made TV broadcast standards
backwards-compatible for over 50 years.

I'm assembling the bits/pieces needed to put together the 40W amp offered up by Mike Kossor in the March/April 1999 QST. Fortunately, the 2 printed circuit boards needed are still offered by FAR. I cannot find a parts placement guide and it is not obvious from either visual inspection of the boards or thorough reading of the article. Anybody have such a thing?? (Wouldn't mind hearing from you Mike if you're out there - nice article)

gary

The League can't help you Gary, but you might try looking up Mike's call
sign on QRZ and e-mailing him direct, lots more likely to get an answer than
a shotgun approach here. That article is getting a little long in the tooth.
You might rather tackle a Communications concepts project, they're a bit
easier to deal with even if Granbergs designs are really old.

I searched but couldn't find anything on:

Using 2 transformers
running the primary of one right off the mains
running the other transformer primary in series
with a large motor run capacitor to phase shift
the primary 90 degrees.
Rectify and filter both secondaries
Diode "OR" the rectified filtered outputs.
This would give me better than double the frequency
As the phase shift would overlap the
120 cycle pulsating DC.

Basicly I have 2 Eico 751 power supplies.
I like to beef up the supply to my Eico 753.

Recommendation for RF Prototype "Vector Board" with groundplane needed

I am looking to prototype a couple of small boards containing LINX TXM-433 LC and LR transmitter modules. These have pads on 0.1" centers and thus will match the Vector board strips that I am familiar with. However for this application, I need a ground plane under the module, and so am looking for a "vector" board with strips, but without plated through holes and ideally a solid ground plane on the reverse side. I would prefer plated traces and fiberglass insulation.

These will be simple boards, a TXM-433-LC, a couple of 555 timers and some discrete components.

Any recommendations?

Three or four ideas:
o Get what you want made by one of the proto shops. Two-sided boards aren't outrageous.
o Use a piece of unetched board stock and glue strips with 0.1"-spaced pads onto it. (Seems like I've seen some places selling strips like that, maybe even with contact adhesive already on the backs.)
o Etch your own. This is close to trivial if you're already set up for it, but since you're asking, you probably aren't, so it may not make much sense.
o Quite useful if there aren't too many pads involved: start with double-sided copper-clad. Score one side as needed with a utility or

XActo knife, and pull up the unwanted copper. I do this occasionally
for SOIC parts, 0.05" lead spacing; it's very quick for small hacks.

Cheers,
Tom

Suggest you run a simulation of your circuit in something like LTSpice. It probably does not behave like you are thinking it will. Transformers are wound with enough inductance that they look like a moderately high impedance in parallel with the reflected secondary load. But if the secondary is loaded with a full-wave or bridge rectifier into a big capacitance, then current flows only when the secondary voltage is greater than the capacitor voltage (by a diode drop or two). So you end up drawing very little current on the primary side, except when the voltage is near the peak. As a result, you don't get a nice phase-shifted sine on the primary side.

Even if the load looks resistive, the current in the load is not 90 degrees out of phase with the mains voltage; it's just 90 degrees out of phase with whatever voltage drops across the capacitor.

Try some simulations with various loads and series capacitor values, and you'll get a feel for what's going on. If you want, I could send you the simulation file I just hacked together as a starting point.

Cheers,
Tom

Also, consider using the E.F. Stahler or equiv. mini-mill bits to
drill out pads on the component side; this is a canonical method
of building high-frequency pcb prototypes. You then have large
copper fill on the component side as well as the reverse side plane.

"Dead bug".

Or, drill holes for all leads, and then use a small milling machine cutter or just a larger drill bit to remove the copper where you don't need it.

For prototyping, "dead bug" is way way superior to vectorboards etc, even with digital parts.

Tim.

Indeed, this is what the Stahler mini-mill bits do; they create an instant
pad wherever it is needed.  Stahler may no longer be in business, but
perhaps there are other pcb fab mini-mill bits out there.  If not, a
good machine shop should be able to create a few for commonly used
pad sizes, and they will be forever useful (to justify the expense).

There was something about making one, I'm pretty sure in "Ham Radio",
sometime before 1974 (I can't figure out which article it was from
an accumulated index). I can't remember whether it was a homemade
version of the Stahler tool, or if Stahler came after to provide a
commercial version.

I can't remember the details (and I don't feel like digging through
the magazines to find the article now), but it wasn't much more than a
piece of good steel tubing.

You won't get 90 degrees phase shift because there's a resistive component involved. And as the resistive component changes, the phase shift will change,

> Rectify and filter both secondaries

OK

> Diode "OR" the rectified filtered outputs.

You don't need to do that, the rectifier circuits do it for you.

> This would give me better than double the frequency

No, it wouldn't. At best it would give you double the ripple frequency.

> As the phase shift would overlap the
> 120 cycle pulsating DC.

At best, the pulses of the phase-shifted rectifier would be in the valleys between the pulses of the non-phase-shifted rectifier. So you'd get twice as many pulses - no more.

What you propose doesn't offer any real advantage over a conventional single-phase supply. But it offers a lot of disadvantages such as requiring more than twice as many parts. The phase-shifted supply will have poor regulation and won't carry its share of the load.

> Basicly I have 2 Eico 751 power supplies.
> I like to beef up the supply to my Eico 753.

The best way to do that is to replace the old diodes and filter caps with modern ones. The 751 power supply is more than adequate to power the 753 if it's in good shape.

If your Eico 753 drifts, it's not the power supply. They all drift, so much so that they became known as the "Seven-Drifty-Three" in their time.

Another option if you can't leave well enough alone is to interconnect the power supplies so that one supply runs the low B+, bias and heaters, while the other one provides just the high B+

As K7ITM says, run some simulations and you'll see the reality.

Hey Jim:

I was getting my transformers and motors mixed up you can trick
a 3 phase motor into running from single phase. But a transformer
is a passive device. Just another pipe dream.

Yes when it was a new built kit: the Ham I bought it from wrote down
all the voltages in the manual, which I still have.
For the 6DQ6 plate supply he wrote down 790VDC in transmitt.

Maybe that's an errot on his part, I get 750VDC in transmitt and
that's with 125VAC input on the mains, With 110VAC on the mains
the plate voltage goes to 650VDC. I put in new caps and high speed
high surge current 3 amp 1000piv diodes in the supply.

Thanks Tom,

Looks like I been just chasing my tail.

I'll have to go with a 3 phase rotory converter.
That's like a 3hp 3 phase motor with phase shift
capacitor plus a run capacitor,
to run a 3 phase 3hp motor from a
single phase.
I then pull 2 phases off the motor
to run my supplys
=2E They use 3 phase rotory converters
to deliver 3 phase power to equipment that has to
have 3 phase power to run properly.
I seen one running on youtube.

Rotary converters in 2008 ????

There are quite a few solid state converters for driving 3 phase bidirectional motors even from as single phase supply at such low power levels.

If the original requirement was to generate sufficient power into a tube transmitter anode supply, I would look into a switching power supply.

There are of course problems finding high voltage rectifiers for higher frequencies than 50/60 Hz and the RF noise might be an issue, but if you can kill the power supply during receive, the RF noise should not be an issue.

This may be too late to help the original poster, but the pad-cutter is still available from a couple of sources. The price is WAY out of line, in my hobby-like mentality.
http://www.vectorelect.com/Catpdf/Page%2071.pdf

The above shows the sizes and styles currently produced. A Goggle search on "pad cutter" or "Vector pad cutter" will turn up some commercial sources (Digikey, etc.), but prices are in the $70-80 range.

A link below shows a neat, homemade version of the same idea.
www.njqrp.org/islanderpadcutter/index.html . While I haven't made one using these instructions, it appears to be workable.

My employer may purchase one of the Vector P138 cutters, just in case I have to fab up something in the tool and die shop where I hang out sometimes. Of course, I could build one, but.... as long as it's other people's money, why not buy!

=========================
A few years ago I bought a few islander-padcutters through the G-QRP
Club.   Excellent for homebrewing with discrete components .
The circular ring removed from the copper clad board is less than  1 mm
wide ,so maximum copper clad area remains ensuring a good ground plane .
Each island can take up 3 component leads
All grounded components are upright soldered into drilled holes , with
the other lead to serve as connecting point for other components.
As an alternative to islands I fit 10 MegOhm resistors upright used as
'insulators' in non-high impedence circuits.

The islands combined with above alternative methods ensure zero to very
short fitted component leads.

Ok, I went through the amp and it is a cheap made piece of junk probably made to power a CB amp. No over current/vpoltage protection except fuses on both the input an output. It does have a few things going for it. The power transformer is truly massive. I dont doubt it would do 50 amps intermittently. The computer grade capacitors are 120,000uf total. The rectifiers were a couple of 25 amp bridges paralelled. I got rid of that and replaced thm with some leadless rectifiers that came out of some old telco equipment. I think they were part of a 200 amp bridge.

The main problem I have with it is the output transistors get hot, they are well heatsinked. The voltage on the collector of the pass transistors are 22volts. I think this is a little high. Is there a good way to bring this down. The transformer doesnt have any taps. I can put a big VARIAC on the front of of it to get it down but this is not my first choice. I think I remember that Sorenson used to make a power supply that used an SCR or TRIAC circuit on the primary side of the transformer as the control element of their regulator.

Any ideas on how to make this a useful device would be appreciated

Jimmie

First off Jimmie I would check out the device numbers on the power
transistors. If a search tells you that they are Darlington devices get
rid of them right off!!!
Darlingtons have a minimum collector/emitter voltage of ~1.5 volts or
more so they will get very hot indeed at 30 amps or so.
The ideal would be to use a switching type regulator and power FET's but
even high current (30 amps or more) bipolar devices would be a big
improvement. Check out the figure for Vce(sat) at high currents, tha
lower the better.
BTW if they are not Darlington devices you might have to use external
transistors to drive them unless you have a very "grunty" zener and
waste a bit of power to give them a reference base voltage.

T&T.Varavoima   [Jarmo Sepp�l�, 04.06.2008]
"Uusi ydinvoimala vaatii nopeaa h�iri�reservi�
Kantaverkkoyhti� Fingrid k�ynnist�� varavoimakapasiteetin rakentamisen yva-menettelyn loppukes�st�. Fingrid varautuu l�hivuosina lis��m��n nopeaa h�iri�reservi� 100-400 megawatilla. "

*��rimm�isen mielenkiintoinen tieto muuten! T�h�n asti kun ydinvoiman pakollista +10% alati py�riv�n tukis��t�voiman olemassaoloa IAEA/USA-lains��d�nn�ss�mme kun on tiedotusvuotona varjeltu julkisuudelta kuin kruunun jalokive�. Mutta kas, KAS n�in vaan Fennovoimalta se MY�S vaaditaan! Ja huomatkaa nyt m��r�! Kerroin, ett� JATKUVAA s��t�apuvoimaa menee 10% ensinn� hukkaan kiinailmi�estoreserveihin ja sitten toinen mokoma p��lle aputukivoimana huikein lis�kustannuksin. Eli t�st� oletetun 2 000MW voimalan 10% kiinailmi�nestoon ja j�lkilauhdepumppujen osasekunttien starttivarmistukseksi alati p��ll� py�riv�n�, ennen kuin ydinvoima edes lain mukaan p��stet��n verkkoon riehumaan menee tuosta siis 200MW. Mutta koska tarvitaan my�s ydintyyliin varmennuksen varmennusta apulis�� p��lle niin lurpahtaa my�s toiset 10% tuosta vaan. Eli TISMALEEN ydinvoima t�ll� faktauksella tarvitsee haaskaavaa lis�voimaa aina ydinalan ammattilaisena kertomani 10+10%= 20%!! Siis JOKA ydinvoimalamme vaatii tylysti todennetusti suomeksi liki Loviisan ydinvoimalan pelk�ksi h�t�apukyytipojakseen! Ja meinaan miljardeja ydintukiaisiin palaa meritt�in!!

*Maailmassa ei toki sitten MIK��N muuu energiamuoto kyll� vaadi vastaavaa reservi�. Ei edes siit� syytt� ydinvoimin aiemmin parjattu tuulivoima. Muilla kun ei s�teilyn j�lkil�mp� r�j�hd� ydinpommina muutamissa minuuteissa ydintyyliin. Esim. vesivoimalalle riitt�� pelkk� maan vetovoimalla toimiva alasajoventtiilin turva, ei MIT��N muuta. Kuten Tanskasta tied�mme siel� ei moisiin tuulis��t�voimiin ole ollut tarvetta. Vaikka L�nsi-Tanskan s�hk�st� on tuulivoimalla jo huikeat 50%. N�ink� alkaa vaan ydinalan valheet tippua julkisuuteen kuin m�t� omena puusta!? Eli nyt vaan Fennovoiman ydinherroilta tiedotusv�lineemme tivaamaan, ett� miksi t�m� ydinvoimaan elimellisesti kuuluneet s��t�voiman lis�kustannusfaktat on aina t�h�n asti vuosikymmenet megakustannuspakkoina pimitetty?!

*Tilanne tulee sik�li hauskempaan suuntaan kun esim. TVO:n kaasuvoimaloiden n.100MW kevytdieselin P�IV�KULUTUS heiluu 1 000m3/vrk. L�p�n euron litrahinnalla korkkaa ekstemporee miljoonan/vrk!! Ja t�m� tosiaan yll� enemm�n kuin triplettin�.. ..Hmm , todella mielenkiintoinen t�h�n asti tarkoin salattu ydinalan lis�megakulu taas paljastettuna!! Ei taida olla "sattuneesti" ydinalalle oikein mieluisaa kertoilla n�ist� reaaleistaan!? Jaa niin tosiaan esim. TVO:n lis�kaasuturbinien pakoputkissa ei laki salli sitten MIT��N filtteri� starttihidasteenaan, eli pelkk� aukko syyt�m��n maailman t�yteen pienhiukkasia ja CO2 sellaisella ennenn�kem�tt�m�n vihan kiivaudella, ett� j�� siin� ydinp��st�kinti�mme CO2 osalta my�s heitt�m�ll�

Farnell used to sell isolated pad cutters. I've got a couple and they
weren't expensive. They might still stock them.

===
There is an excellent article on SCR controlled power supplies in ARRL
mag QEX -July/Aug 1999 ,pages 50 - 55.
"A regulated 2400 V Power Supply by VE6AXW"
It has a 'soft start' facility and voltage control is very good (voltage
drops only a few volts between zero and 1 Ampere load conditions (and
that at 2400V)).
The SCR or triac type of control can obviously be applied to any power
supply unit . It can hence also be used for a controlled (soft start)
filament voltage for expensive high power valves (tubes)

In order not to get a 'dirty' 115/230 V AC system on the premises
,because of the SCRs /triac ,it might be necessary to include an
'upstream' AC filter.

Cliff-

Are you sure that applies to Astron-type power supplies? The ones I'm familiar with do not operate with the pass transistors near saturation.

Perhaps a Darlington device is not the best choice for some other reason, but I would think a pair of 50 Amp devices could handle 15 Amps each (30 Amps total) with sufficient cooling, if they are rated for at least 120 watts each. (I assume 22 volts input, 14 volts output, 8 * 15 = 120 Watts per device.)

>K4DII

Fred is absolutely correct in saying that the pass transistors in most linear regulators such as those in the Astron supplies do not operate as saturated elements. Therefore, the higher CE saturation voltage of a darlington has no bearing in this discussion. On another point, the 120 watts per device that Fred mentions is at a case temperature of 25 deg, C. Heatsinks of reasonable size can't dissipate that much power and keep the case temperature at 25C.

I have a few talking points that nobody has touched on directly.

If the regulator was designed to use normal (non-darlington) pass transistors, and you substitute darlingtons in their place, some very bad things could (will) happen.

The output of the regulator will likely try to go to its full input voltage rail (because of the high gain of the darlingtons). The feedback loop in the regulator will try to bring it back down to the set output voltage. It probably can't because the gain of the darlingtons is too high, and the output stays banged against the input rail (22V).

Even if the regulator loop can bring it down, the control loop isn't compensated correctly for the high gain of the pass elements, and the regulator will oscillate wildly. Both conditions are catastrophic for a power supply.

Another point that I would like to mention is that of a transistor's SOA or Safe Operating Area. There are two graphs in the datasheet for the transistors. The SOA graph shows the safe combinations of collector current and collector-emitter voltage AT A CASE TEMPERATURE OF 25 DEG C. The power derating graph shows how much power the transistor can safely dissipate at a given temperature.

You MUST use thesse graphs when designing a pass element. They will help you choose the appropriate transistor types and will tell you how many transistors you have to use in the pass element to safely supply the design load current.

In almost all cases, the current through each transistor in the pass element is limited to much less than the absolute maximum collector current spec. Thus, although a 2N3771 transistor has an absolute max Ic of 30A, it won't be able to pass that amount of current at any value of CE voltage. The datasheet gives the conditions for that current; the higher the collector current, the lower the CE voltage allowed.

Sorry for being long-winded, but it's not a 2-sentence discussion.

Cheers!!!

Are you sure about that ? Have you looked at the capacitor voltage with an oscilloscope with full nominal current and minimum mains voltage ? The goal should be that the capacitor voltage just before the rectifier starts to conduct is only slightly above the output voltage.

The SOA is important especially in the short circuit current limiting case, when both the current and voltage across the transistor is high. A fold-back current limiting solves this problem.

The SOA derating usually starts above 5 V, so in a properly designed power supply the input-output voltage difference should be less than that, so in normal operation, the SOA is not very critical.

I dont understand what you mean by this. The voltage gain of the darlington transistors is less than unity in this case since they are being used as emitter followers.

I am dropping 8.5 volts at 20 amps or 170 watts is being dissipated by the transistors. This may not be a real problem. I know my commercial power supply of similar size only provides about 18 volts to the collector of the pass transistors and this would result in about half as much power being wasted. What voltage would you normally expect at the the collector of the pass transistors. I have also thought that maybe I dont have that much of a real problem since I doubt if the power supply will ever be put under the same demands as it does working into my load bank. Also I think I should add two more transistors in paralell with the two I have. I think this would distribute the heat better over my heat sink and have less localized heating.

I dont think the size of my heatsink is a problem, it is probably overkill. it is a 8in chimney type heat sink(i think that what you call them) 8x8x10 inches finned inside and out. The transistor body is mount on the outside withe the wires going down the inside of the chimney. The end of the chimney is designed to take a muffin fan.

Jimmie-

I agree. Being the devil's advocate, a circuit can have parasitic elements you don't think about, and can oscillate in a different mode than it normally operates in. If you were using it to power a transmitter with a poor antenna, there might be some RF energy entering the base-emitter junction. The energy is rectified and shifts the bias conditions. DC output voltage is changed, resulting in a change in the level of the rectified RF, resulting in a change in the DC output voltage, et cetera. Normally you would disregard this until/unless you actually observe a problem.

I agree with Paul, that you want the capacitor voltage to be relatively close to the output voltage. But there is a limit where hum starts to appear in the output, and regulation is reduced. In the case of the Astron RS-20 circuit diagram, the main capacitor voltage is listed as 23.0 for no load and 18.0 under load, for 13.8 VDC no load output and

13.7 VDC under load.

I worked on a friend's RS-20. After repair, I ran it for several hours
at 8 Amps load. This is within the continuous power rating, but the
heat sink really got hot!

I thought you guys might be interested in my current restoration of a
30s "homebrew"
receiver. I put homebrew in quotes because I'm not 100% sure it's not
commercial built
or maybe a prototype.
Here's a like to the first of the project web pages.
http://radioheaven.homestead.com/HomeBrewRX.html

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

                    FLEA all SUMMER at MIT
                    Sunday July 20th 2008
                          9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take place on the third Sunday of each month this summer, April thru October.

There is tailgate space for over 600 sellers and free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if you're lucky enough to have a copy of our ad) and sellers spaces are $20 for the first and $15 for each additional at the gate.

The flea will be held on Albany between Mass Ave and Main streets in Cambridge; right in the Kendall Square area from 9AM to 2PM, with sellers set-up time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly, will be admitted FIRST.
Separate lines will form prior to gate opening for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered well illuminated tailgate area is available for all sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776 (M-F 9-5)

********** $1 buyers discount with hard copy of this notice ************

<FF>

Mail the coupon below by the 5th to be a Prepaid Vendor.

FLEA at MIT 2008 Rates

SELLERS

To use your prepaid spaces the named vendor MUST be present.
Rates include one admission per space.

```
Advance         $17 First space
                  $12 Additional Spaces
                        Must be received by the 10th of the month.

Gate Admission  $20 First Space
                  $15 Additional Spaces
                      Admission is after the prepaid vendors.

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
                ** You may not sell. **
                $15 per person at the gate.
                $70 Season Early Bird Buyer

   cut and return

The voltage gain of darlingtons is less that unity as a emitter
follower. but not the current gain. The base current is like 20 ma.
and the collector is like 20 amps that's a gain of 100. A good
regulator like a LM723 can regulate that easy. If the gain ain't there
in the darlingtons you need a drive transistor.

I use a 0.1 ohm 50watt resistor series with the output, that gives me
an extra 2 volt drop that isn't across the transistor and keeps 40
watts from heating up the output. You still lose 40 watts. It just
goes up in the resistor. The 0.1 ohm 50 watt is only good for like 22
amps.

Put a fan on the heatsink. 170 watts will get hot all the time.
I put a computer power supply fan on my supply, the output stays alot
cooler.
Once the current drops the fan cools it really fast.

You have a high transformer voltage because it's a 50 amp supply and
you are running it at only 20 amps.

Huh, I thought the 723 was a voltage regulator, not current. Im sorry
but what you are saying just doent make sense to me. It is my
understanding that the greater current gain of the Darlington
transistors is just going result in the 723 seeing a lighter load wich
would be godd for the 723. Perhaps that could be a problem if it were
light enough, maybe this would result in the 723 becoming unstable but
this does not appear to ba a problem with light loads, no loads or
heavy loads.
When I first started working on the power supply there was one tiny
problem using the Darlingtons that was more a result of the poor
design of the origonal circuit than anything else. The the origonal
circuit monitored the ouput voltage at the base of the pass
transistors. Because of the 1.6 base to emiter drop of the darlingtons
the output voltage was a little low. After moving the pick off point
to the emitter I no longer had this problem.

I added two more pass transistors and this seems to have helped a lot.
I was once given a rule of thumb that a TO3 transistor should never
have to handle more than about 7 amps continously. I was pushing them
to 10amps. Even though they are rated at 50A they will not handle
anywhere near that without extreme measures to keep them cool.
Interesting note, at 40amps they dont get is hot with 4 transistors as
it did with 20amps with 2 transistors. I didnt check yet but I suspect
that is because the voltage at the ouput of the filter rectifier is
beginning to drop off a bit. If I continue to try to use this power
supply  I would probably increase the number of pass transistors to 8.
This would be easy to do as the existing heatsink is already prepared
for it.

Thanks much for the advice
Jimmie

Hi All,

I am building another one of my toys http://tinyurl.com/6x3a9m and need a couple more two pole Gigafil thro hole filters centered around 785Mhz - 795Mhz, I need this for the RX LO for Base Station receiver. The last one was scavenged from an old AMPS phone, see http://tinyurl.com/626k4c.

Yes, I know that this isn't quite ham radio, but it is experimentation just the same...

If anyone can help with either parts in the junk drawers, or know of a supplier I will be most grateful. SMT parts will work at a pinch.

This is a non-commercial project.

Thanks,

Mark

Hi Andre,
there are any number of circuits out there on the web - Google is your
friend. I did this a while ago, but cant find the URL on my ever more
congested hard drive....lots using PICs, which is fine, but some used
a 555 for a spot frequency.

Andrew VK3BFA.

I bought an old Heathkit IG-42 "Laboratory Generator" at a flea
market
the other day. It powers up OK but I don't have anything to test it
with except a TEK 465 O-scope. I looked for an output with the scope
but couldn't find anything. I know the scope is working because its
1K hz calibration signal looks fine.

The generator dial goes from 100 KC to 30 MC.   Is this too high a
frequency to be monitored with a 465?

Lets look at all of the original post that I responded to while you
deleted what the issue was about. Here it is:
******************************
From arthures@panix.com Tue Jun 24 16:39:43 2008

Did any of you guys look at http://groups.google.com to see if what you want
is there? There are lots of ways to connect to NG servers that are outside
of your network (unless they disable nntp protocols).

As a guy who is presenting himself as: i) non-clueless, ii) complaining
about OT posts and everyone else who is clueless, I think your own
knowledge leaves much to be desired, and iii) your habit of deleting
relevant other material from another poster has the effect of quoting
out of context. You also deleted this part that I authored:

*****************
From arthures@panix.com Wed Jun 25 23:57:59 2008

Whether your post gets "out" far onto the net depends at least to some
degree on where on the net your ISP is located and what kind of traffic
flows there. I've had experience with about a dozen UNIX shell account ISPs
over the last 15 years and in the past there were quite a few that did _not_
```

have good connectivity with other ISPs through the nntp protocol. I'm not overly happy with Google for NG access, but if anyone is unhappy with their own ISP's NG server (they can subscribe or block whatever NGs they feel like) then certainly they should try Google. And, you can even use Google (and other "portals") to find other NG accesses.

****

Too much
> spam, but too much cluelessness. People posting from google without
> any awareness of where they are. People posting from google without
> quoting what they are replying to. People posting from google and
> being clueless about how others see the newsgroup,

As I tried to explain, nntp is not like email. A post goes out in all directions to neighbor ISPs. It is supposed to be relayed to the next nodes, and re-relayed from their. Many years ago I could watch a post start from a point of origination and start appearing at farther out ISPs sometimes hours later. If the local ISP does not _subscribe_ to that newsgroup, then you won't get any posts. If posts don't appear within some upper limit in time, then those posts will never appear period. I am not aware that any ISPs sellectively reject a few or all nntp posts from any source, but many will reject emails based on domains of origin because of spam. ISPs out on remote branches of their network connectivity are the ones that have the poorest "capture" ability and one of my ISPs had such a poor connectivity until they upgraded.

so they think
> doing things like replying to spam with an empty message but a different
> subject header will "fix things";

ISPs can handle thread content based on the subject line or the reference in the header to the original post that the author is responding to.

the rest of the world sees an empty
> message that requires effort to figure out what the post is about since
> we don't see it all on one webpage.

This is your best comment. However, certain newsreaders will group response posts, whether it included some text from the prior post or not, in its proper place in the thread subject (eg. Free Agent). PINE (a Unix newsreader) does not keep response posts in a thread so changing the subject has no effect. Google puts the response post in the same thread and _sometimes) mentions that the subject was changed that the original post was made under. Also, what you see with Google depends on what kind of web browser you use.

However, there are a lot of people who don't follow the courtesy of quoting what they are responding to. Usually these people don't have anything important or significant to say, anyway.

Google has made it too easy
> for people to post to Usenet, so they can post without giving any

> thought to what already exists.

Such as the relevant material I wrote that you deleted. For a free service, Google does a lot for people. The problem is that people are either not knowing what they are doing or refuse to use good operating practices when trying to carry on dialog. My observation that most conversations are neither informative or cooperative seems to indicate a fairly widespread deficiency in human intelligence.

> They too often think a newsgroup
> is a hangout,

This is a description of the reality about newsgroups rather than any error on the part of NG posters and lurkers. NGs really are hangouts, just like bars.

> where anything goes

This is also a description of reality (unless you want to belong to a moderated NG or a website chatroom where you can get censored by the owner/manager, and be exposed to advertising, malicious code being downloaded on your box, and your logins going into a database).

so long as everyone shares the
> common interest of the newsgroup.

There is very little "common interest". Spamers come to spam. Bloggers come to harvest people off NGs to go to their blog. Everyone else has their own agenda. I know what some of the agendas are and skip over those and go to the next ones.

SO rather than find a newsgroup
> where a post is on-topic, they post where their "buddies" are.

And, I think this is just fine. If a guy doesn't like some post, he can't say anyone forced him to read it. Ultimate freedom of speech.

> With each little bit, the newsgroups degrade just a little bit more.

Trouble is, there are also a lot of guys out there who are self-appointed judges of what is on-topic or off-topic, what is right and wrong, and they constantly bitch about everyone else while they play the roll of NG-cop and say everyone but themselves is doing it all wrong.

> Drive out the ones who know what they are doing, and then the clueless
> can do whatever they like.

You can also start your own group or mailing list, and invite all of the people that you find acceptable and play the game called "snob," too.

OOOPS! My bad! :-)

Yes, LINEAR TECHNOLOGY CORPORATION did LTSpice...an improvement over their previous SPICE derivative done to promote their switcher ICs.

Apologies all around to Linear Technology friends. They make fine ICs.

I also have, but have not tried TINA from Texas Instruments, another SPICE derivative. Not enough time here to try everything out that is available. TINA is also free for download but it is harder to get through their web pages to do so.
I don't have any friends at TI or Linear or at National Semi, I just use their good products...just like I am currently using a couple of

LM337s using National's
appnote information in a slightly different way.

73, Len AF6AY

Anybody have a MathCAD, Excel, Scilab or Octave worksheet for designing with the CD4046 or 74HC4046 PLL chips? I'm looking for something that allows one to input desired VCO frequency, offset or center frequency and loop frequency with bandwidth. The worksheet should generate the required component values. I can do this by hand but I have a lot of test cases I want to investigate so doing the calculations by hand is a bit time consuming. I don't want to spend a week doing a worksheet up from scratch if somebody has one they are willing to share.

Some links to PLL design software:

This one is a spreadsheet application:

http://www.keystoneradio.com/?n=Main.PLLDesign
Download the last version of the spreadsheet to get all the improvements.

This one is a web-based JAVA application:
http://webench.national.com/appinfo/wireless/webench/index.cgi

An old DOS program, but seems to be pretty good

I have a 12volt home made power supply similar to Astron models. I was told it could handle 30A. The pass transistors are missing and I have some 50 amp NPN darlington transistors on hand I was considering using for replacements. Can you think of any reason these could/should not be used.

Jimmie

Tons, but all of them start with 'maybe'.

The biggest one is 'maybe your power supply was designed for straight transistors' -- if it seems to have hefty current drive to the pass transistor bases, then that would be the case.

Otherwise, go ahead and put in your pass transistors and see what happens.

Keep in mind that those pass transistors may be missing for a reason, and the reason may be that the power supply never worked well in the first place -- so if what you have doesn't work, it may be the design or execution of your circuit, not the transistors themselves.

>be used.

Some of the Astron power supplies had a separate (higher voltage)
power supply for the control and driver stages and the input-output
voltage difference could be as low as Vce(sat) i.e. below 1 V, thus
the power dissipation could be minimized.

However with a darlington, the minimum voltage drop would be Vce(sat) for the driver transistor and Vbe for the big transistor, thus requiring a higher transformer secondary voltage and hence suffer a large dissipation in the series pass transistors.

Note also that even if the darlington could handle 50 A, the power dissipation for TO-3 packages are typically in the 100-150 W range so a single transistor could tolerate only 3-5 V voltage drop at 30 A. However, those power dissipation figures apply for 25 C case temperature, so in practice, this could be achieved only if the transistor and the heat sing is submerged into running cold tap water:-).

So in practice, you would have to use several darlingtons in parallel with large heat sinks and also use larger emitter resistors to balance out the gain differences between darlingtons. This may require a slightly higher transformer secondary voltage.

Good day all!
I have an old Kenwood TS-820 that I've already upgraded somewhat, but I
would like to try adding the WARC bands at 10,18 and 24 MHz.
The rig only cost me $50 so I was horrified when I discovered that
crystals for the job are now priced @ $65 US each + shipping!!!
The frequencies aren't very unusual so obviously I am looking for
someone who has them available for a more reasonable rate.
As it stands it just isn't worth the cost of over $250 NZ.
The Xtals are on 15.5 23.5 and 30 MHz and are standard miniature types.
If any one can help me out please drop me an Email and let me know how I
can pay for them.

Cliff -
You will note that many homebrewers prefer to use widely available "microprocessor crystals" for all crystals. Typical prices are $0.50-$2.00 new, and they are widely available from lots of distributors (in the US: Mouser, Digikey, etc.)

30 MHz is a widely available microprocessor crystal available in many holders.

The other two frequencies you want are not microprocessor crystals, but nearby frequencies are available, and if you don't mind the dial reading strangely will work fine. If you've added an outboard counter, some are smart enough to do the math between the VFO and the hetrodyne crystals and it will automagically read correctly. (Small plug: look around and you'll find such smart dials for as little as $10.00).

23.512 MHz is widely available (I think it can be divided down to be a baud rate generator which is why it's a "microprocessor crystal".)

15.36 MHz is also widely available.

While the microprocessor crystals are not the most pristine high-Q crystals available with matching-Kenwood parameters, they will work just fine for hetrodyne oscillators.

Andy writes:

Look in the tech manual for a spectrum analyzer that covers a few Khz to 1.3 Ghz and you will see exactly how it's done.

Typically, the LO runs above 1.3 Ghz and all signals are converted UP to a high IF where the first filter is a wideband SAW. A SAW can have several Mhz bandwidth way up there.

Then the signal is downconverted to an IF that is compatible with the SAW bandwidth to achieve image rejection. The IF filter here is usually something like a crystal or ceramic filter, unless the requirements
for instantaneous bandwidth forces a better group delay response.

The hardest part is keeping the signal linear (intermod, crossmod)
in the presence of multiple simultaneous signals until the SAW and next IF filters are reached.

Lots of tradeoffs have to be made.

These tradeoffs have already been made in spectrum analyzers, so if you get a few different block diagrams of different units, you will
see what specific frequency plans the designers have decided to use.

The frequency plan of the cheapest spectrum analyzer would probably fit your purpose....

Coming up with a good frequency plan in view of the nonlinearities of the mixers used and the bandpass characteristics of the filters one employs is a real challenge sometimes.

Andy in Eureka, Texas

JAN Crystals in the US will make these up for you, as will International
Crystal Manufacturing.  They're both on the web.
```

Dunno what difficulties you'll have getting them into New Zealand.

You may want to check to see if there are any crystal manufacturers in other countries that may have what you need at less cost -- I'm really only familiar with these two.

Hi,

I would like to build a PCB board with fine pitch (LQFP32) and very small surface mount parts (1206 and smaller) parts. The board is a simple 24 bit A/D and D/A converter with a full speed (12 Mbs) USB2 interface; although I would prefer the USB2 high speed interface (480 Mbs). The temptation is too hard to resist using today's microprocessors such as SiLabs C8051F350 (basically an 8051 cpu). I know that a commercial 4 layer PCB with a solder mask would probably work for homebrew construction; but the board cost is high.

So what is the chance of a double sided PCB without solder mask working with very small parts? The process I would use in either case would be:

1. Place solder paste on all pads. Typically, when heated the solder will vacate between pins and will suck up, like a magnet, under the SMD pin.

2. Place glue under parts that will possible move when the board is handled.

3. Heat the PCB in a toaster oven until soldered. Manually follow the heat up and cool down time curves for type of solder paste used.

Comments/suggestions are appreciated.

LQFP32 is not ridiculously fine pitch (I do 0.65mm pitch parts by hand
all the time), and 1206 is just enormous in the SMT world.

I do both by hand all the time - just a Weller WTCPT with 0.015"
solder. No solder mask for me (I use ExpressPCB cheapo boards) but
pretinning does help. Sometimes flux comes in handy but is not really
necessary. Just lay the solder down across the leads, melt on with the
soldering iron, go back and clean up any blobs with solder-wick.

Toaster oven is great for BGA's but if there's only a few leaded SMT
parts it seems like way overkill.

Try http://www.quartslab.com/ , they are happy to supply radio amateurs
and can provide any frequency to order for a fair price. (less than $20.00)

I don't have any problems making PCBs at home for 0.5 mm lead spacing
QFPs, or soldering them. by hand (drag soldering).

Leon

"Tim Shoppa" <shoppa@trailing-edge.com> wrote in message
news:8fd5be5c-7d6c-43ee-8afa-fbff3a953e37@y38g2000hsy.googlegroups.com...

LQFP32 is not ridiculously fine pitch (I do 0.65mm pitch parts by hand all the time), and 1206 is just enormous in the SMT world.

I do both by hand all the time - just a Weller WTCPT with 0.015" solder. No solder mask for me (I use ExpressPCB cheapo boards) but pretinning does help. Sometimes flux comes in handy but is not really necessary. Just lay the solder down across the leads, melt on with the soldering iron, go back and clean up any blobs with solder-wick.

Toaster oven is great for BGA's but if there's only a few leaded SMT parts it seems like way overkill.

Tim N3QE

Thanks for the reply.

You are correct, a 1206 is a large SMD component and I will try to use them wherever possible. However, smaller (0402 and larger) may also be used. It is encouraging to hear about successful fine pitch results with hand solder techniques. In addition, it will certainly be useful for parts placed on both sides of the PCB.

Thanks for the reply. I have though about using a laser printer to print a negative image on clear Mylar. Then expose a photo sensitive PCB to the negative image. The laser printer does print very sharp lines as visible using a 10X loop. The quality should be good enough for fine pitch. The etching process however may end up in disaster with fine pitch lines.
How do you make the PCB?

For my purposes, 0603 is the "standard" size SMD part to use when I
have a choice. Of course power parts are gonna be bigger.

I mean, just so you don't scare yourself, look at the bottom of a
TO-92 transistor that you've been soldering for 30 years or more. The
pitch there 0.05 inches or 0.127 mm. And you do those all the time.
Your LQFP is finer pitch, but not ridiculously so. So don't set
yourself up with the mental attitude that it's gonna be hard, because
it isn't going to be hard!

I have occasionally used 0402 and even 0201 parts when they weren't
available in 0603... I struggled with 0201, and 0402 required a lot of
concentration. By comparison the 0.65mm pitch parts were a piece of
cake.

And finally, don't ignore the option of doing "dead bug" with SMT
parts. Very fun for low-lead-count analog parts... and possible though
questionable for digital stuff with lotsa leads.

Tim.

I use an inkjet printer and JetStar Premium film for the positive
artwork. UV exposure on Fotoboard 2 with pre-coated resist and etching
in ferric chloride.

I agree with Leon and Tim that making a board and mounting parts on it shouldn't be a problem, though I do greatly appreciate being able to do my soldering under a stereo microscope using a Metcal iron.

I commonly use boards coated with positive resist (from Circuit Specialists in the Phoenix area), etched by floating them on top of ferric chloride. I find that (lacking a spray etcher) the float process maintains fine line resolution--I have a theory that it has to do with copper-laden etchant being heavier and falling away from the etch site, but whatever, it works well for me. Surface tension will hold fairly large boards up, but you can also just put support at the corners and let the board submerge. Resolution for me is always limited by the quality of the transparency. Thanks to Leon for posting a reference to another film material to try. I've had the best luck using an Epson inkjet printer: my HP printer doesn't do as well, and laser printers typically don't print a dense enough black. Pinholes WILL print on the board! I use a back-light film setting on the Epson for highest density. An alternative is to get a photoplotting shop to do the film for you: better quality but it lacks the immediacy of being able go from layout to board in minutes. Anyway, the best inkjet printed transparencies will allow me to do 5 mil lines with 5 mil spaces if I'm careful, and 8/8 pretty easily. Most of my work is with 0805 as the standard passive, since that's what I invested in an assortment of back a few years ago, but I also do 0603 with no trouble, and lead pitches down to 0.5mm. We have fancy equipment to do BGA rework here at work, and the trained techs have marginal success with it at best (for large parts), so I've avoided BGAs in my home projects.

By the way, if you get boards from Circuit Specialists, be aware that what they call 1 ounce copper is really 0.5 ounce...seldom a problem and allows faster etching and it's easier to make fine lines, but be aware of it for high current traces.

Cheers,
Tom

I use a Metcal and microscope, as well.

I use manual agitation in hot FeCl3. I don't have any problems getting
down to 8 mil tracks or even less.

The ordinary JetStar film is suitable for dye-based ink like that used
in Epson printers. Premium Jetstar is intended for use with pigment-
based inks used with HP printers. They are available from Mega
Electronics and Farnell.

===
If the design of what you have is 'debatable' and having NPN Darlintons
which require relative low drive current you might consider a very
simple circuit with a LM317 in a wrap-around circuit.

That's what I do. Then I transfer the layout to fotoboard2 by exposing
to my sunray for 5 minutes, and etch with sodium persulfate. Perfect
results. And soldering 0603 by hand is really no problem.

Sam

These seem to be UK suppliers.  So far, my Google searching hasn't
turned up a source in the US for the JetStar films, though I am
intrigued by the product lines that Valley Litho carry.  There's been
something of a revolution in how printing is done:  professional laser
printers are used for short runs, offset plates are made in various
ways much more directly from computer-generated copy, and laser and
inkjet printers are used to make positive and negative
transparencies.  Valley carries several items that claim to produce
dense, clean copy for exposing plates or screen film, and that should
be fine for PCB work too.  I'll probably call them to get
recommendations, since a hundred sheets of transparency film is a bit
pricey to buy to just try out.

Cheers,
Tom

Not to mention the ARRL handbook, which has several choices in their
power supply chapter.

Silkjet film seems to be similar and is available in the US. They even
make two types for dye and pigment inks, like Mega do. It might be the
same stuff, renamed for a different market.

Thanks, Leon! I really appreciate your inputs that have gotten me pointed in some new directions. Maybe all this will get some other folk experimenting and reporting back their results. First: Silkjet is a brand of Kimoto, so if you search for Kimoto you may find more suppliers and info. (They also make high quality laser printer film.) Second: if you do searches like "screen printing inkjet film" you'll find a bunch of stuff. My belief is that a film that's really suitable for exposing screen printing emulsions is very likely going to be suitable for transparencies for PC printing. Also, I found one place at least that offers a ten-sheet sample pack of Silkjet (recommended for Epson printers) for $10; I just ordered one--they seem to not have a minimum order, even. (shop.poconoscreen.com) And with the right supplies, you may be able to do as well (or better?) with a laser printer; see for example the Valley Litho web site -- and a search on "screen printing laser film" turns up lots of stuff too. The key seems to be finding out where inkjet and laser printed transparencies are being used commercially, and screen printing is clearly one of those areas.

Cheers,
Tom

Tim I made a few repairs that were obvious and discovered the power
supply design was minimal at best. It does have what seems to be a
very heavy duty transformer probably 30 amps CCS. There is no
overcurrent/overvoltage protection. The heat sinks are small in
comparison to my Pyramid brand 20 amp power supply. The transformer is
center tapped but a paralelled pair of bridge rectifers are being used
with the (-) leads disconnected. The regulator doesnt have its own

power supply or even operate from higher voltage taps on the transformer. Oh well, I bought it for the transformer and it looks like I got a good deal on that and the box.

I don't spend a lot of time using the internet to go to ham radio related websites, but at least one website I know about runs at a financial deficit and not enough human resources so that might be part of the problem. There could be technical reasons, too. But, I, at least, would appreciate knowing if you still have this problem repeatedly in the future.

For what it  worth almost any 3 legged regulator will work in this
circuit. The minimum voltage of the power supply will depend on the
voltage of the regulator. Basically the LM317 is a 1.25 volt
regulator.

Jimmie

Both sites come up promptly for me here today. I've seen them be quite
sluggish in the past, but that's not the case just at this moment.

===========================
The LM317 ,being basically a 1.25 v regulator can have a variable output
by means of a potmeter or any fixed output by means of 2 fixed resistors
  ,that's why it is often used as a universal device.

Yes, VoiceMax is selling well. We are unable to keep up with the
demand at this time. These units are back-ordered until late August08.

sound more like the garbage that fell off of the BACK of the animal while it
was taking a CRAP.  OH - wait a minute - "back-ordered" - that is the
convention that you go out and turn-around and order something?

Linear Technology has recently introduced an interesting new regulator that should get the attention of experimenters wanting a variable bench supply that goes easily down to zero volts. You can consider it an amplified emitter follower with max offset of a very few millivolts, along with a precision 10uA current source feeding the input pin. So you hook a variable resistor between the input pin and ground, and the output voltage is R*10uA. It's also acceptable to drive the input pin with a voltage source, such as the output of a DAC, if you want. Guess I should mention that it's the LT3080. The design choices that went into it make it easy to parallel, and also easy to add a "pre-regulator" so that the '3080 doesn't have to dissipate all the power when delivering low output voltage from a high unregulated input. (No, I don't work for them...just think it's a cool part.)

Cheers,
Tom

They're not really denying you access; they're just no longer running a
USENET server as part of their ISP business any more. You can still get
to those groups ... you'll just have to pay someone else for usenet
access. (Or get it for free from, say, aioe.org, or use google's lame web
interface, etc.)

As such I don't think this is something for the law to be involved in.
Verizon's decided to drop part of their service, but there's room in
the world for crappy ISPs alongside the good ones.

If Verizon decided to start blocking access to other companies' news
servers, or forge reset packets, etc., the way Comcast (allegedly?)
does, then you'd have something to write your representatives about.

You might be able to get out of any contract you have with them, on
the basis they've changed the service without renegotiating...
people seem to do that for cell-phone contracts a lot.

U.S. Consumer Product Safety Commission
Office of Information and Public Affairs
Washington, DC 20207

FOR IMMEDIATE RELEASE
July 2, 2008
Release #08-319

Firm's Recall Hotline: (800) 843-7422
CPSC Recall Hotline: (800) 638-2772
CPSC Media Contact: (301) 504-7908

RadioShack Recalls Power Supplies Due to Electrocution and Fire Hazards

WASHINGTON, D.C. - The U.S. Consumer Product Safety Commission, in cooperation with the firm named below, today announced a voluntary recall of the following consumer product. Consumers should stop using recalled products immediately unless otherwise instructed.

Name of Product: 13.8V DC Power Supplies

Units: About 160,000

Importer: RadioShack Corp., of Fort Worth, Texas

Hazard: The recalled power supplies are wired incorrectly, posing electrocution and fire hazards.

Incidents/Injuries: None reported.

Description: The recall involves RadioShack 13.8V DC Power Supplies, catalog numbers 22-507 and 22-508 with date codes from 08A04 through 01A08.

Date code format is MMAYY where MM is the month and YY is the year. The catalog number and date code are located on the back of the power supply. Power Supplies with a green dot on the product and the product's packaging have already been repaired and are not included in the recall.

Sold at: RadioShack stores nationwide from October 2004 through January 2008 for between $50 and $85.

Manufactured in: China

Remedy: Consumers should unplug the recalled power supply immediately and take it to any RadioShack store for a free repair. Registered owners of the recalled power supplies will be mailed a notice.

Consumer Contact: For additional information, contact RadioShack at 800-843-7422 anytime, or visit the firm's website at:

http://www.radioshack.com/recall

To see this recall on CPSC's web site, including pictures of the recalled products, please go to:

http://www.cpsc.gov/cpscpub/prerel/prhtm108/08319.html

He'd better review all the fine print in his contracts, updates,
references to disclaimers, and consider that those high powered lawyers
have an interpretation somewhere that lets them do this and almost
anything else without recourse to the user.

Hello to all and thanks for reading.

I am seeking info on a source for inexpensive modem transformers for use in a PSK31 type interface. A few years ago I purchased surplus ones for less than a dollar a piece, now the only ones I can find are $3 to $4 a piece.

Any info for these 600 to 600 ohm transformers appreciated.

Howard

Discarded modems are an obvious source of cheap modem transformers. Just keep an eye out for computers waiting for the garbage trucks, and then open them up with the screwdriver you should carry for such circumstances, and pull out the modem boards. You don't even have to open them to see if there's a modem, just look for a pair of phone jacks on the back. A lot of those modems nowadays aren't that much more than the phone interface, the main CPU doing the work, so there's no real loss in using such modems to supply the transformers.

Cordless phones are easy to find at garage and rummage sales, for a dollar or two. All the base units will supply a transformer, though maybe not as small as the ones in the modems.

Find a surplus outlet that has piles of boards, and that may be a source if they let the boards go cheap, since you just have to pick out the modem boards.

Hi Jim, Tim and Steve!
Thanks for the reply. I had of course considered microprocessor crystals
and in the case of the 30.00 MHz one this wasn't a unusual frequency.
However many units these days come with an integral oscillator.
I had tried several Xtal companies in the US and elsewhere but the price
as I had pointed out was a bit "out of sight" for such an old rig. Also
I have had a lot of trouble with US companies in both my hobbies, Ham
radio and Amateur astronomy with overseas orders.

Owing to the 820s' rather odd IF frequency (~8.3 MHz)the heterodyne
crystals are rather critical if dial and counter calibration is to be
maintained.
Very fortunately however I was contacted by Ric VK7RO in Tasmania who
had both the higher frequency units "gathering dust" from a similar
project and he not only very generously and kindly donated them to me
but pointed me in the direction of an Australian Xtal company who can
make me the 15.5000 Mhz crystal for less than half the US price and one
third the delivery time. I hope to have all the cystals to put the 820s
on 10, 18 and 24 MHz in the next week or so and then will get the job
underway. As I have never worked the WARC bands so far it will be a new
experience for me !!

Cliff, I'm glad you found a source.

And going with an in-country company is good for that sort of thing,
when you can find it.

Well, not quite OM. I'm in New Zealamd and about 2,000 Km from Tasmania.
We are still an independent country so far . Hi!!!
Cliff

Hello,
in an old VFO project that I'd like to duplicate (seems easy and
stable enough for me), the inductors (2) are specified as a number of
turns on a 5mm former with
"purple core". Now I know what a 5mm former might be, but I surely
don't have any idea what a purple core is and how to recognize it on
my parts department :-)
Any info is appreciated, thanks in advance.

Francesco IZ8DWF

Some company in Europe that was popular with amateurs made ferrite or iron-powder cores and color coded the mixes. Purple doesn't match the color codes for Micro-Metals cores that are available in the US, so it's not one of theirs (or it's an obscure one).

You may be able to figure out the inductance, and make the inductor some other way. This takes away some of the 'easy', but it's at least a method.

If you can post the schematic and the operating frequency somewhere, someone here may take a stab at suggesting an inductance.

Or wait and see if someone in Europe or with experience with European parts gives you a response.

Well, actually the inductances should be approximately 76 nH and 9.2
uH according to the frequency range of the VFO. But not having a
reliable method to determine cores characteristics from the ones found

on the parts box, I'd rather identify the good cores in some other
manner.
The long way will be just winding some (random?) number of turns on
random cores and see where it goes to oscillate, if oscillating at
all :-) But it's true, it's not as easy as before, and still wouldn't
tell me if the selected core is well suited for the frequency range
I'm interested in.

Neosid coil formers and cores have always been popular in Europe. They
are still made, but it can be difficult to buy them.

Leon

The following link will take you to some of the Denco (and other manufacturer's) data sheets about the old coil formers and dust-cores.

http://vintageradio.me.uk/info/dencocoils.htm

Hope this helps

Derek.

I have sent the following to Verizon. I hope more do the same. They are eliminating access to all but 8 supergroups.

Why are you deleting perfectly good newsgroups from your service? I routinely access the following"
alt.autos.jaguar
alt.autos.subaru
alt.engineering.electrical
alt.ham-radio
alt.os.linux.ubunt
rec.radio.amateur.homebrew
If my access is denied, I will encourage my Senate and House delegations to enact legistation that will restore my legitimate access to these groups. I think the last thing you would want is more legislation on your networks.

Al

Thanks Tom

I will try. DIY is my fun
Now in my test circuit is a cheap mechanical front panel encoder.
Only 16 steps/rev.
It doesn't satisfy me.
Shaft has no bearings in  mounting and it has inconvenient play.

Unfortunately, nothing to do with the net is a protected right, it is a
privilege. Most ISP's don't even know what Usenet is let alone carry
it.

I buy blocks from Octanews, because while my current ISP has access, they
cap it at 16Kb/s. Makes downloading mp3's on my cellphone faster. Octanews
blocks aren't limited as to speed, just Mbytes.

Good luck!

=============================================
Purple coloured toroids are for example Ni-Zn ferrite type 4C65 made by
Philips.
For inductors used in frequency determining circuits (vfo), powder-iron
cores are normally used .

Ferrite for RF applications is usually applied in chokes , baluns, ununs.

I am currently building a radio - sound card interface for my IC-730 so i can use PSK31. AIUI, the mic that came with the rig contains a preamp, so presumably the radio is expecting an audio level above a usual mic. Does this mean I can simply use the audio level from the sound card straight into the Mic input on the radio via a 1:1 transformer for isolation, with no need for a voltage divider to bring the level down?

Thanks.

Actually it's a contractual agreement between you and your ISP, but realistically most "consumer grade" ISPs promise nothing -- no guarantees on speed, services, ports, uptime, etc.!

You might try access via google (groups.google.com) and web browsing. Also, look at other ISPs. There are a lot out there. Lots are more friendly to the old "free" internet spirit. I use www.panix.com quite a bit of the time. There are many others.

====================================
Transformer does not need to be 1:1 exactly
Suggest you include an approx 1000 Ohms trimpot to fine adjust the mic
port input from the transformer. Assuming the radio audio input
impedance is in the order of 500 Ohms.

Please note that a single trafo only in mic line doesn't isolate
satisfactory.
Otherwise there will still remain humming earth loops.

If your rig has a phone patch or a line input it is preferred to use
these. You need not to play with plugs .
In many rigs the VOX is not controlled via line input. In that case PTT
rules on the air.

Be ready to use a trafo also in headphone output line and a relay or an
opto isolator for PTT.

It is most simple to use COM port RTS or DTR for PTT.
KISS: Connect a high bright led and a 5V dil relay in series directly
into RTS. Led is very nice to show "On the Air".

Hi Postipoika,

Unfortunately, my rig doesn't appear to have a line input, so using
the mic connector looks like the only option.

I had already planned to use another transformer to isolate the
headphone socket on the radio from the soundcard, and an optoisolator
on on RTS for PTT, although I may get away with just using the VOX.

Right now I am using AT&T (bellsouth) DSL. If they drop the news groups
and Comcast doesn't, I think bellsouth will lose both my phone and
internet business. It's nice to have TWO providers of the same service
competing with each other!

=======================================
Agreed, this is rather OT ,but if you have a (A)DSL connection with a
provider in the USA , do you have to 'sit out' a say 12 months contract
before you can switch or can you switch at any time ?

I wish you'd respond to the question of how many feet you
need. I received your email, but you never answered the
question of how many feet a "short length" consists of.

Tom -

That is correct, the low-gain or "zero" models (last digit in model number
being zero of sold-state late 1970s /early 1980s vintage radios) from Icom
(IC-730 being one) ..... did have this problem (pre-amp was in microphone
and inside the radio on the input)
http://www.heilsound.com/amateur/tips/all_icom.htm

You are correct in that you MAY not need the voltage divider -- having an
adjustable input such as that with the Jim Mitrenga, N9ART sound card
interface "A Flexible Digital-Mode Interface".  BTW, although that
RadioShack relay is no longer available -- there is an NTE equivalent that
is a "drop-in replacement".

From reading the occasional data sheet and appnote, I have the impression
that (as Tim Wescott says) they upconvert to a high IF, like 3 GHz,
and then convert down from there.

In that case they might have an LO that tunes from 1.7-3 GHz, which is
a much smaller range, proportionally, than 100kHz-1.3GHz.

My Yaesu FT-857D and FT-817ND transceivers use a PLL and DDS. The PLL cleans up the DDS output and the DDS gives the fine tuning.

The 857 receives up to 450 MHz, and uses a 68.33 MHz first IF.

Leon

Hi All;
I've been saving this for years but now realize that I'll never get to build a small CW Xmtr so its time to move it to someone who can put it to good use.
Stancor(Chicago Transformer Co.), Model PC8411, 4 hole, above the chassis mount, enclosed.
All wires are uncut & original length, some surface rust on the laminations, Bells are fine as is the yellow label.
Primary Voltage = 117V. 60 Cy.
Secondaries= 375-0-375 @ 150ma dc
Filiment= 5.0v @ 3A.
Filiment= 6.3v @ 4.5A
Weight shipped about 8.5lbs

```
Price is $60.00 with Priority mailing .
Will make a nice transmitter supply.
Tnx & 73.......
Rich WA2RQY/4

Did any of you guys look at http://groups.google.com to see if what you
want is there? There are lots of ways to connect to NG servers that are
outside of your network (unless they disable nntp protocols).

For various transmission types, how much group delay variation can be
tolerated in
the receiver before it causes problems recovering the original
signal?  I realize that it
all depends ... I'm just interested in getting a rough idea.

For example, at what point is:

  1) SSB voice reception noticeably affected?

  2) the ability to receive images from weather satellites affected?

  3) various amateur radio modes such as PSK31, RTTY, and MFSK16
affected?

  4) HD Radio specs 600 ns as the max for the transmitter, what's the
max for the receiver?

I'm curious since the group delay variation of SAW filters available
for IF filtering seems
to vary widely.

I have been playing with homebrew crystal filters (following W7ZOI and
Bill Carver/K6OLG) for CW, as well as audio filters, and can tell you
that on CW the difference between a super-sharp-in-frequency
Chesbyshev filter (typical in ham equipment for a long time now) and a
more constant-delay (e.g. Gaussian to 6dB or 12dB, or equiripple
linear phase) filter is like night and day.

My impressions are done "to my ears", not to a spectrum analyzer.

The super sharp in frequency Chesbyshev filters have horrible horrible ringing especially on say 40M or 80M in the summer with the QRN. I can hardly listen for a few minutes without getting disgusted. BUT... they do have a real advantage during say a contest when there's competing signals every few hundred Hz.

At the other extreme the constant-delay filters sound remarkably clear and transparent. They do not have such a sharp stopband, but my ear makes up for that most of the time. Ringing from summertime band noise is not nearly so tiring.

Most of the filter simulation programs (AADE, SPICE, NatSemi's cool new WebBench filter tools, etc.) let you look at not just frequency response but also phase response and (maybe most importantly for summertime QRN) impulse response. Having run the simulations and listened with my ears to my experiments this summer, I cannot emphasize how much more enjoyable it is to use a Gaussian-to-6dB or equiripple linear phase filter in CW.

Often when the bands are not crowded but there is QRN, I far far prefer a simple two-pole crystal filter designed for CW in the first place (e.g. my Heath HW-16) to any fancy-pants 8-pole or 12-pole modern filters in my new rigs.

I notice you ask about a lot of digital modes but not CW. My ears have been listening to CW for 30-some years now and I can do a lot of processing in my brain. But what my brain cannot remove is horrible filter ringing. I don't know how those other digital modes stack up... maybe computers are better at removing horrible ringing than my brain.

I don't think I have a "golden ear" or any other audiophile quality. In fact I'm pretty sure my ears are less good than they were when I was a kid doing CW.

You wouldn't happen to know the group delay variance
of the filters you mentioned? Rough values are okay.

I believe that in theory if the exact group delay profile is known,
then
a digital receiver can perform a certain amount of equalization. What
I'm curious about is how much varience can be introduced by the
filters in a receiver for various transmission types without needing
to equalize.

I haven't actually measured group delay but I'm sure that what I hear is group delay.

If you look at published group delay graphs for commercial Chesbyshev filters, a 500 Hz 8th-order crystal filter has a delay around 2ms in the middle of the passband, but within 100 Hz of the edge of the passband the delay peaks up enormously to 4ms and then back down again over the very steep skirt.

Maybe you can turn the 2 ms variation into some inter-symbol/intra-symbol limit for some digital modes. It rings like the dickens when hit with QRN, that's for sure!

Tim N3QE.

Pa. debunks rumors of =91speeding ticket frenzy=92
By Peter Mucha

INQUIRER STAFF WRITER

An e-mail making the rounds warning of a Pennsylvania crackdown on speeding is a mix of fact and fancy, according to state police.
The message sounds an ominous alarm:

"BULLETIN! BULLETIN! BULLETIN . . .

"Starting today, Pennsylvania will launch a 30-day speeding ticket frenzy. The state estimates that 9 million dollars will be generated in speeding tickets."

Judging from the date of the e-mail, "today" meant last Thursday.

"Look out for Penn dot trucks parked along the road or appearing behind you pacing you," the e-mail warns.

"It could be a Trooper driving the truck, it is called 'Operation Yellow Jacket' and will be off and on all summer."

Better keep that cruise control to 2 m.p.h. over the limit to be safe, the e-mail advises.

Actually, this ticket-frenzy e-mail is nothing new.

In April, state police issued a press release advising that it's all a hoax.

"The misinformation in this e-mail is an urban legend that originated in New Jersey in May 2005," the release stated. "Since then, the hoax has targeted police in several other states."

Yes, troopers give tickets to speeders, said Sgt. Edward Murphy, station commander of the Dublin Barracks. But no, there's no special crackdown on speeding this summer, he said.

Monday was, however, the start of a two-week campaign called Smooth Operator in Pennsylvania and New Jersey.

The program, which targets aggressive drivers, has been conducted periodically in Pennsylvania since 2006.

But the e-mail is correct about one thing: Operation Yellow Jacket does exist, Murphy said.

"It's a statewide program," he said. "It's the use of PennDot vehicles to run radar from."

The vehicles are generally parked at the side of the road - not necessarily in work zones - but are not used to pace motorists, he said.

The program's purpose is not just to catch speeders but also to remind motorists to be careful around any work crews and emergency vehicles.

"They should be slowing down when there's anything on the side of the road," Murphy said.

Under the state's Steer Clear Law, motorists are required, if reasonably possible, to move out of the lane nearest to construction crews, police making traffic stops, or tow trucks assisting disabled vehicles.

Anyone who receives the hoax e-mail should delete it, state police said in its April press release.

"The Department suggests that anyone who receives such an e-mail to simply delete it," the April press release continued. ". . . The Department never issues traffic citations as a way of raising funds for the state."

I have access to three non-Google ISPs and in recent months, the posts
have been getting out to all of them just as fast as I can log onto them
by telnet and check for myself. They have improved over, say, a year ago.

Whether your post gets "out" far onto the net depends at least to some
degree on where on the net your ISP is located and what kind of traffic
flows there. I've had experience with about a dozen UNIX shell account
ISPs over the last 15 years and in the past there were quite a few that
did _not_ have good connectivity with other ISPs through the nntp
protocol. I'm not overly happy with Google for NG access, but if anyone is
unhappy with their own ISP's NG server (they can subscribe or block
whatever NGs they feel like) then certainly they should try Google. And,
you can even use Google (and other "portals") to find other NG accesses.

You miss the point, though I'm tired of seeing all this off-topic
discussion in every newsgroup as the clueless post about it rather
than know what's happening and finding the right place to post.

He's saying that many will filter out posts from google.  Too much
spam, but too much cluelessness.  People posting from google without
any awareness of where they are.  People posting from google without
```

quoting what they are replying to. People posting from google and being clueless about how others see the newsgroup, so they think doing things like replying to spam with an empty message but a different subject header will "fix things"; the rest of the world sees an empty message that requires effort to figure out what the post is about since we don't see it all on one webpage. Google has made it too easy for people to post to Usenet, so they can post without giving any thought to what already exists. They too often think a newsgroup is a hangout, where anything goes so long as everyone shares the common interest of the newsgroup. SO rather than find a newsgroup where a post is on-topic, they post where their "buddies" are.

With each little bit, the newsgroups degrade just a little bit more. Drive out the ones who know what they are doing, and then the clueless can do whatever they like.

Excuse my ignorance, but why on earth do you do some crude analog
filtering and then continue with digital filtering, in which you have
much more alternatives ?

The only reason that I can think about using sharp IF crystal filters
is that the dynamic range of the following stages (product detector
and ADC) is not sufficient.

In a typical general coverage up converting receiver, the roofing
filter will define the bandwidth the ADC must handle. Also some gain
control (not necessary automatic) is needed to set the band noise well
below one LSB (LF/MF vs VHF/UHF and antenna efficiency on LF).

Even when designing an add-on unit for audio processing, why would
anyone use the receiver CW filters apart from dynamic range issues ?

I kind-of have the same questions too. For a homebrew project, having all the software-designed-radio complexity in addition to the tight-analog-filtering-from-DC-to-daylight complexity seems to just... make everything too complicated and not fun anymore.

But the best ham receivers couple impressive front ends with effectively tight roofing filters with SDR aspects effectively (and quite usably) and I can see why someone would want to try their hands at their own competitive design. But, wow, it's a lot of effort. And a lot of ham receivers - especially the first and second generation designs - combined all these technologies into radios that are actually painfully complicated to use. (When the QST review starts contrasting menu option 73 submode 4 with menu option 105 submode 13, that's a real turn-off to me. At the same time, other younger operators just love that sort of complexity!)

On the other hand, a truly simple analog front end (e.g. Softrock) combined with a computer is a hell of a lot of fun. You spend a lot more time looking at a computer screen and less listening but that's what some like.

Tim N3QE.

To undersample the signal it must be bandwidth limited which means
some
type of analog filtering.  As long as filtering is necessary, it might
as well be a narrow as the widest signal of interest and as sharp as
possible so long as it's convenient and doesn't distort the signal too
much.

> why would anyone use the receiver CW filters

Probably a bit narrower than what I had in mind =85  I'm currently
looking
at 500 KHz wide SAW filters.

"As long as filtering is necessary, it might as well be a narrow as the widest signal of interest and as sharp as possible so long as it's convenient and doesn't distort the signal too much."

"As sharp as possible" and "doesn't distort the signal too much" are somewhat conflicting goals: In general, the steeper the skirts of a filter, the more group delay variation you get there at the edges (hence, Butterworth has less group delay variation than Chebyshev which has less than Elliptic). Now, you can certainly account for this by widening the passband a bit and then perhaps using even steeper skirts, or you can compensate for it digitally if you can characterize it, but the main point here is that it does get rather complex -- hence the trend to have somewhat "looser" analog filters (and thus low group delay variation) and then do whatever you want digitally.

Understood, part of the point of this thread which was to get an idea of how much group delay variance is acceptable for various types of transmissions without greatly impacting the quality of the received signal.

> hence the trend to have somewhat "looser" analog filters (and thus low
> group delay variation) and then do whatever you want digitally.

Also understood, it's all about balance. Going narrow impacts group delay variance which distorts signal, going wide impacts dynamic range.

Which still leaves me with the notion that you want to go as tight as reasonably possible and no tighter. With that in mind it sounds like what we've determined so far with regards to IF filtering is:

```
  transmission type             receiver group delay variance
  -------------------------------------------------------------
    CW                          should be less than 2 ms
```

this is based on Tim Shoppa's posts which were to the point.
Does anyone else have data to contribute?

As a rough guesstimate, the group delay in a 500kHz wide filter will be 1/500,000 secs, or 2.0 microseconds. Now, depending on shoulder steepness the change in group delay might get to 2, 3, maybe even 5 times 2.0 microseconds. But even at 20 microseconds I don't think any of the HF digital modes you mentioned would be impacted.

Most of my comments regarding group delay and ringing in filters were oriented towards narrowish (few kHz or less) filters.

Wow, a HF receiver with a 500kHz SAW filter after the mixer. I don't have a clue what you're doing! I thought we were talking about HF receivers for common bandwidths!

Thanks ... that's the type of information I was curious about.

> Wow, a HF receiver with a 500kHz SAW filter after the mixer. I don't
> have a clue what you're doing!

I'm "playing" with something resembling 0 - 175 Mhz up converted to
208 Mhz
filtered using a GSM SAW filter sampled at the first IF using a 25
Msps 16 bit
ADC. The silly width is because I'm interested in handling broadcast
FM
including RDS (among other things). I'm also interested in receiving
satellite
images which in some cases has a bandwidth of 150 Khz.

"Does anyone else have data to contribute?"

I don't, and I suspect that no one has done a comphrehensive survey of various popular (to hams) modulation formats and their sensitivity to group delay variations. Doing so would definitely be valuable -- it'd be a shoe-in for a QST or QEX article.

>
> Tim N3QE

Obviously, both the time and the frequency response are determined by the positions of the poles and zeros of a linear system (filter), but be a bit careful about equating group delay and ringing. It's easy to make an FIR digital filter that has constant group delay, but rings quite nicely.

I suspect the people who design RF communications systems using modern modulation schemes know the answers to John's questions. There's probably another newsgroup where you'd get more answers. Or--run some simulations. I can imagine creating ideal signals in Scilab (or Matlab) and feeding them through various filters, and then demodulating them. It shouldn't be terribly difficult to do that, but I'm not volunteering.

Cheers,
Tom

'Ringing' and group-delay over a passband are separate things but, in
practice they are are related. In passive-component filters they are
quite related.

'Ringing' phenomena can be investigated analytically in any time-
domain circuit analysis program. I use LTSpice from National Semi-

conductor...totally free for download and works on any PC. SPICE compatible, the source stimulus can be set as a pulse of several cycles with the rise-time, fall-time adjustable. If there is electronic-cause ringing, it will show up at the output.

Every single passive-component filter has time delay. If the time delay is unequal across the passband, then one will hear the ringing. Such ringing isn't always a physical-electronic thing IN the filter but more in the way the human brain perceives sound. True high-fidelity electronic music systems will have near-equal time delay over its entire passband. Unfortunately, few, if any, of the first Hi-Fi systems makers ever published specifications on group-delay or delay of any kind. [excluding speakers, of course, since those and their interrelationship with a room are so acoustically variable that no common standard could be reasonably adopted]

It is very hard to describe sound that is FELT rather than measured by instruments. As Tim said about CW use, ringing causes an actual discomfort. With wideband home music systems there is very little perceived 'ringing' but there exists 'quality' which can only be graded by comparison with another system as 'A-B' testing. The one that FEELS like it sounds best would be the winner.

For non-audio use, such as in AM-PM ('QAM') modulation combinations in modems, inter-symbol distortion with/without an 'eye' display can grade things...and group-delay effects aren't the only things to blame there, lots of others in the total path.

Simpler FSK systems such as single-channel teleprinter need concentrate on group-delay only over a passband about twice the frequency of its frequency shift between Mark and Space. Group-delay there shows up more on demodulated pulse edge ditortion. Ringing there can be seen easily at the edge transitions. A compromise there is to have group-delay greater beyond the needed passband limits resulting in rounded transitions; demodulator output can be shaped afterwards as desired.

NTSC analog video examples do not really apply since the common ACTUAL bandwidth of most smaller TV sets was so limited (down to 1 MHz in some) that group-delay effects are hidden in the resulting video passband distortion of details on objects.

Broadcast FM is hard to define in felt-quality since FM's 'quiet' spectrum use is relatively narrow. 'Loud' passages of music uses more spectrum space, thus group-delay effects over a passband are more pronounced on loud passages.

>... I can imagine creating ideal signals in Scilab (or
>Matlab) and feeding them through various filters, and then
>demodulating them. It shouldn't be terribly difficult to do that, but
>I'm not volunteering.

Machine-in, machine-out systems such as teleprinters and modems can be compared relatively easily with computer analysis programs. Regardless of the computer program, none can substitute for what is FELT in the ear-brain sensory system with acoustic input. I see a valid test as only A-B or A-B-C (or more) comparisons using the same audio or audio-modulation input. That is a LOT more work. Most of what I've done in that delay subject are locked into lab notebooks in corporate ownership and it involves many man-weeks of investigation. The best one can hope for, in my estimation, are general guides on limits from the many and varied radio services.

It just occurred to me that many don't know what "group-delay" is. It is physically-electronically a time delay from input to output that may vary depending on the input frequency versus the magnitude-phase response of the filter within its passband.

Group-delay is defined as the difference in phase delay versus frequency difference over very small differences in frequency. Most analysis programs show that as a matter-of-course using frequency-domain analyses. Using around 50 or more different frequencies of a linear source sweep input will show the actual filter time-delay, input to output, that is very close to the real thing.

I'm playing with 600V ex-PSU MOSFETs (with very high Ciss) as HF switching finals, with some success.

I'd like to put together a driver that takes sinusoidal input into a fast voltage comparator, and produce a variable pulse-width low-Z output that could be used to efficiently trim the output power.

With such a driver, a suitable slow data stream into a DAC could be used to generate a variable control voltage that could in turn cause the RF output to vary as to conveniently simulate ionospheric fading. (Just kidding. I promise).

I read specs of many possible ICs types but I am at loss as to which common and inexpensive types may be suitable, and found no examples of specific types used in that specific role.

I had klutzed with DC-offsetting a sinusoidal signal into an ugly nonlinear driver to that effect, but the idea of using a comparator is from Paul Harden N5AN (who is CCed):

http://www.aoc.nrao.edu/~pharden/hobby/_ClassDEF2.pdf

Any suggestions?

Also, did anyone press into HF service a standard suite of PWM and MOSFET driver ICs used in automotive applications?

I saw operating frequencies in the order of 400kHz, but with driver transition times in the 10-20ns range, which is already promising - although perhaps I would not try them on a MOSFET totempole at 10MHz, or at least not right away...

TIA!

Filippo N1JPR/I2

What is the dB advantage of this vs. RF clipping for SSB?

Something just occurred to me.

We don't *know* that Strip-X was discontinued because of health/safety/
environmental/"do-gooder" issues. That's pure speculation.

It's quite possible - in fact, probable - that the reason Strip-X was
discontinued was lack of sales. After all, the *professionals* use
solder pots, not chemicals. Amateurs who are in the know use solder
pots, or a solder blob.

I suspect that the market for Strip-X was so small it wasn't worth
producing any more.

But as I wrote, we don't *know* that such things got rid of Strip-X. I
say it was solder pots.

Correlation isn't causation. Unless a controlled study is done that eliminates other variables, a causation is not proven. For example, it could be that those who eat lots of salted and smoked fish also tend to eat lots of something else, and it's the something else which is the real cause.

The "known to California" jargon means such controlled studies have been done.

> > Did every user of the stuff do so in a "well-ventilated area"? I think

Of course. And people have to read them!

Why? It's the same concept: reduction of avoidable risk.

The point is that the *professionals* who made the cars resisted safety improvements that we now take for granted.

> I have long advocated such radical technology as
> strong roll cages, 5 point seat belts and fire suppression systems on
> automobiles if we want to get serious about safety.

A roll cage isn't needed if the car structure is built strong enough

(roof won't collapse if car rolls over)

True harnesses are a good idea, as is fire suppression.

Hydroflouric acid is *really* nasty.

The Big Issue IMHO is whether a dangerous process can be made safer. Is there a safer way to silver a telescope mirror?

There *is* a safer way to remove enamel from wire, and you get the added bonus of a tinned wire. Why use a chemical at all?

Related topic:

The EU has regs that are essentially outlawing lead solder in electronics. Because the EU is such a big market, most electronics makers are following along, and rather than deal with both lead and no-lead solders, they're going all-no-lead. With all the problems lead-free electronic solders bring along.

But IMHO the whole thing is wrong-headed. Lead in the environment is a problem, but the solution is recycling, not banning lead.

How ironic is it that a major rework of a car's electronics will be done to eliminate a few ounces of lead-tin solder, while the car's battery contains many pounds of lead and acid?

==

Indeed ,lead free solder does not flow that well even at elevated
temperatures ,
so I have stocked up on leaded solder (possibly sufficiently for the
rest of my home brewing life).

But the point is that electronic equipment having printed circuit boards
contain a very low percentage (weight wise) of solder. If that solder
contains lead any recycling effort to recover/isolate the lead will be
exceedingly costly. In the past printed circuit boards were pulverised
to recover the gold on 'contact fingers' through a chemical process ,
but apparently that is no longer viable.

So although there is very little lead in electronic equipment manufactured with 60/40 or 63/37 leaded solder ,when equipment ends up in a land fill the cumulative effect is bad ,poisoning ground water.

So it does make sense to go for lead free solder.

BTW : In the UK leaded solder is still available ,although no longer from High Street retail outlets like Maplin Electronics .

Lead Acid Batteries have a large percentage of lead (weight wise) ,hence recycling is commercially viable .

Filippo -
You should reconsider trying to PWM your RF switching amplifier. If you are running Class-E, changing the duty of the drive signal will not affect your output power significantly, but will destroy your efficiency if you deviate from 50% duty.

With Class-D power amp, you can PWM the drive to control output power, but it is very stressful to the MOSFET. However, there is a way to do it, see US patent 7092269.

Good luck, keep us updated.

73 - Dave NM0S

We have been seeing signs all over for people buying gold jewelry. This past weekend my wife knocked some talk out of one of these guys, and they said they still do recover gold from PCBs, but right now, buying old jewelry does result in a source of gold for about 1/3 the market price.

I've used it once. That's just about enough, IMO.

> The Big Issue IMHO is whether a dangerous process can be made safer.
> Is there a safer way to silver a telescope mirror?

Not specifically using silver. More common these days is sending the mirror away to have an aluminum or other coating flashed on it in a vacuum chamber. Pretty safe, but not many people are going to do that at home. I did it mainly for the experience, and to do an extended field check of the quality of the mirror. Checking out a mirror is not unlike checking out an antenna. Usually we do a star test on an uncoated mirror. We install everything in the tube, and look at stars to determine if the work we did was acceptable. But just like propagation affects how an antenna appears to work or not work, the sky conditions can affect how images look in the eyepiece. So multiple sessions are best, but no one wants to wait a long time, so most people check it out once, put in a fudge factor for how they think the seeing will be, then ship it out for aluminizing, and hope they guessed right. Sometimes they don't guess right.

I gave my mirror almost a year worth of test. I knew it was a veery good mirror after a month, but then I just continued the experiment to see how long the silver would last, since they are very fragile surfaces.

> There *is* a safer way to remove enamel from wire, and you get the

Just need to interject that solder pots aren't completely benign.

>
> The EU has regs that are essentially outlawing lead solder in electronics. Because the EU is such a big market, most electronics makers are following along, and rather than deal with both lead and no-lead solders, they're going all-no-lead. With all the problems lead-free electronic solders bring along.
>
> But IMHO the whole thing is wrong-headed. Lead in the environment is a problem, but the solution is recycling, not banning lead.

Agreed. There are ways to remove most all the lead from circuit boards during a recycling process. Electronics can be designed and built with an eye towards recycling; easy disassembly, etc.

On the lead replacements, I have an old solder information book. Lots of the new replacement metals are shown in it with examples of why those metals aren't used. They were considered bad contaminants.

> How ironic is it that a major rework of a car's electronics will be done to eliminate a few ounces of lead-tin solder, while the car's battery contains many pounds of lead and acid?

Didn't think about it before, but now that you mention it, it is kinda dumb.

I think that machinery can be developed to handle lead removal, we
already have ways of getting the solder onto those boards in rapid fashion.

I think we aren't looking at it in the right way. Changing over is going
to cost - probably big time. We are going to have to put up with
increased failure rates, whether through solder joint failure, or
reduced component life due to added heat stress.

After all, if lead free solders were the best way to go, that's what we
would be using. So we'll be retooling and spending that money for an
inferior product. Maybe Devo was right!

And, we're saying that this new lead free solder is going to be safe to
dump in landfills. M'kay, if they say so.....

The compression ratio of VoiceMax is fixed at 15:1 with distortion
levels well below 1%.
I suggest you read this for clarification... http://en.wikipedia.org/wiki/Au=
dio_level_compression

|
|What is the dB advantage of this vs. RF clipping for SSB?
|
|
|----------------------

RF Clipping is superior to audio compression in SSB transmission. RF
clipping will provide about 6dB improvement over audio compression
alone.

james

Revision: 1.1 2007/09/29 18:42:47
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

```
 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups
 Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
 Last Posted: 9 Nov 2001 06:18:17 GMT
 Posting-Frequency: 15th of each month
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

```

I think a lot of electronics folks have done the same.

```

Whether it's viable depends on the rules. Here in the USA, a number of states require a deposit (usually five cents) on beverage containers. That deposit is typically far more than the intrinsic worth of the metal, glass or plasti in the container, but that's not the point. Instead, the deposit makes it worthwhile to collect and recycle the containers, keeping them out of the trash stream and reducing litter. Why couldn't there be such a deposit on electronics?

> So although there is very little lead in electronic equipment
> manufactured with 60/40 or 63/37 leaded solder ,when equipment ends up

All sorts of things wind up in landfills that are far worse than the small amount of lead solder in electronics. Are the metals in lead-free solder all benign?

> So it does make sense to go for lead free solder.

I think there are better ways to keep lead out of the trash.

> BTW : In the UK leaded solder is still available ,although no longer
> from High Street retail outlets like Maplin Electronics .
>
> Lead Acid Batteries have a large percentage of lead (weight wise) ,hence
> recycling is commercially viable .

But does that guarantee no lead or cadmium containing batteries of any kind wind up in landfills? Just one car battery in a stream is far more contamination than a very large number of PC boards.

IMHO, the big problem is that electronics of all kinds is becoming a throw-away item, with short useful lifespan, but recycling lags far behind. The problems of lead-free solder may make the lifespan shorter, and so the disposal problem worse.

I think you'll find that auto batteries are already VERY commonly
recycled, for exactly this reason.

On Jun 6, 2:00=A0pm, NM0S <ai9e_...@yahoo.com> wrote:

> If you are running Class-E, changing the duty of the drive signal will not affect your output power significantly, but will destroy your efficiency if you deviate from 50% duty.

Thank you, Dave!

My understanding was that duty cycle would set output even in class E.

I like to gather silicon from the recycling heap, and although I have IRF510's, my current victim is a SK2545, wrung out of a PSU, Pd=3D40W, Vdss=3D600V, and Ciss=3D1.3nF (!) not easy to stress - actually, that's exactly why I opted for that class of device, only partly fit for purpose, but forgiving, and easy to find.

I already wrung several watts of RF out of at 10MHz it with decidedly ugly and bad drivers which I did not manage to run in switch mode. They heated up a lot, but the final got sufficiently "overdriven" to partly go switchmode, and did not heat up that much.

I have a totempole ready with complementary BJTs from a printer driver (2SA2037 / 2SC5694, 60V, 7A, 300MHz), they need .85Vbe to go into saturation.

Ample current is needed to quickly charge and discharge the MOSFET gate, I reckon it'd take ~ 250mA, hence the driver'd better be switching too rather than overheat in linear mode. So, duty cycle aside, I need a clean square wave.

MOSFET gate must be swung from <3V to >10V, driver bases need >8.5Vpp.

I could use a 74HC240 line driver for VXO and amp, enough current for a IFR510, surely not for Ciss> 1000pF, but OK for the complementary pair.

Yet a comparator would indeed be ideal. With it I could one day also futz with duty and see by myself what happens... [read John 20:29].

Now, off to read US patent 7092269! :-) After all, I am shooting for class D, not E. I want to design a frequency flexible matching and filter network to cover many bands with few components, perhaps resorting to old fashioned variable capacitors, E would be way too complicated anyway, and efficient output throttling would be nice to have.

Does anyone have a suggestion for a common and inexpensive type that works well throughout HF?

Now I see my error w.r.t. class E: by moving the switching actions along the cycle you can't possibly time them for the [I=0, V=0] points.

Still ruminating on class D.

One of the biggest problems I have with the lead free solder is that over time it tends to grow tin whiskers. Then it shorts out to adjacent pads. Current reliability requirements are to encapsulate all the solder joints with epoxy. This is painful and really causes problems with rework.

No-lead; a feel-good solution to a non-problem.

Erich N6FD

Sigh...so written communication from the manufacturer is 'no good?!?'

Oh, yes, it must be so. "Southgate Radio" (that big, big maker of radios) hasn't issued a Proclamation yet to 'confirm' the fact.

>It's quite possible - in fact, probable - that the reason Strip-X was
>discontinued was lack of sales.

No one seems to have checked out General Cement and its line of products. They've been in business for over 75 years, have regular product displays and stocks at NON-ham electronics stores. Many of those products have LOW sales rates. Their original product, an acetate-based cement (originally intended to repair paper speaker cones) is still in the current catalog (but under a different product number than the original). Who 'repairs speaker cones' these days? One can expect them to carry it for nothing other than sentimental or nostalgic reasons given that there are MANY kinds of cements available in NON-electronic stores that could do the job as easy and probably better. It is, as acetate-based, no different than hobby cements such as 'Testors Cement' also made in the same city by by Testor Chemical Company (also still in business for about the same time). It is incredibly cheap to produce, costing no more than the original LEAD-based tube both used to come in. Yes, youngsters, Testors Cement and GC chemicals and every toothpaste made by anyone once came in LEAD tubes! [horrors! contamination!]

One thing that you youngsters ASSUME is that insulation on magnet wire has ALWAYS been the same to this day. Not true, but it is impossible to tell some of the middle-aged knowitalls so (they passed a code test in their teen years and have been extra class a long time...harumpphhh).

At the introduction of 'wire-wrap' techniques (both in telco infrastructure and in prototype digital PCB card construction), roughly around the beginning 1960s, magnet wire manufacturers were beginning to use LOWER-TEMPERATURE-MELTING insulation of various kinds. "Solder-Eze" is one brand name that was very successful...there are dozens of others. Look in any Kings, Times or Belden full catalog.

PVC (PolyVinylChloride) insulation has been used on wire at the end of WWII. PVC has a low melting point (relatively speaking). MIL-W- specs of nylon-jacketed PVC wire was standard US military wire in aircraft of the late 1940s. The nylon jacket adds resistance to abrasion and has a higher melting point. Relatively easy to mechanically strip nylon-jacketed PVC and it does not 'collapse' from melting if soldered too long using manual wiring. With petroleum more abundant after WWII, other polymers were developed and used, notably Teflon (TetraFlouroethylene) which was relatively indestructable compared to predecessor insulations.

Hughes Aircraft Company El Segundo Division (made radars and fire control systems for military aircraft) had surplus nylon-jacketed PVC wire at their employee's store. I used some of that to nearly-completely rewire the electrical system of my restored 1953 Austin-Healey sports car in 1958. Much better wire than the cotton-cloth covered gutta percha insulation of the original English wiring.

>After all, the *professionals* use
>solder pots, not chemicals. Amateurs who are in the know use solder
>pots, or a solder blob.

REAL "amateurs who are in the know" got their materials experience IN the electronics INDUSTRY. Especially those who who were involved in materials testing and design of both electronic and physical construction.

By the way, this "Southgate Radio" you keep mentioning doesn't seem to exist as anything but the name of a store up in Canada. There IS a Southgate Amateur Radio Club in the Southgate section of London, England...but their website doesn't seem to have much on magnet wire stripping techniques. Lots of new solid-state radio information there for radio amateurs, though.

>I suspect that the market for Strip-X was so small it wasn't worth
>producing any more.

SPECULATION! SPECULATION! When did the 'radio manufacturer' from 'Southgate Radio' ever visit GC or get a PROFESSIONAL chemical lab to analyze what was in there? BTW, how many radios does 'Southgate Radio' make each year?

>> We do have a system that is pretty good. The MSDS reports are pretty

>> product is know to the State of California as a carcinogen" type stuff.
>>
>> I wonder how many people called up the state of California to talk about
>> that?
>
>bwaahaahaaa

Tsk, tsk, easterners back in PA making fun of the most populous state in the USA...and once the capital of the aerospace industry in the USA. It is also the state with the MOST licensed radio amateurs in the USA.

>> > What does "do-gooder done did too much with all those warnings and

>> warnings. What I do mind is when a useful product goes away.
>
>But as I wrote, we don't *know* that such things got rid of Strip-X. I
>say it was solder pots.

If you DO say that, then you are NOT an "amateur in the know."

LOWER TEMPERATURE magnet wire insulation used in the electronics industry enabled newer techniques of stripping insulation and the use of 'melting by solder pot' VERY SMALL VOLUME production technique...or connections by mechanical means that both broke through insulation and made electrical connection. The "push-down" rapid connection system for telcos is an example. Much, much quicker to do, less labor intensive. Look at many of the multiple-wire cable connectors that use a mechanical crimping system to join every wire at once and also make an electrical connection.

The predominant method of stripping magnet wire in the electronics industry is the abrasive brush method which ALSO works for small gauge insulated conventional wire. They don't fool around with labor-intensive, one-of-a-kind techniques of construction used by hobbyists.

Manufacturers of electric motors might use propane gas torches to BURN off stator windings' magnet wire, heating it enough to bare the copper and to solder to it in one operation. Same thing for some (but not all) rotor windings. Electrical motor makers use magent wire by the MILE and make them at relatively low cost...and for very long life in high-torque AC powered applications.

>The "known to California" jargon means such controlled studies have
>been done.

Spoken by Pennsylvanians without ever once doing any 'controlled studies' of any subject involving California. Sigh...

>> For me at least, the comparison of mechanical with chemical issues is a
>> little hard to work.
>
>Why? It's the same concept: reduction of avoidable risk.
>
>The point is that the *professionals* who made the cars resisted
>safety improvements that we now take for granted.

AFTER a whole bunch of litigious actions by those who were trying to make personal profit via civil suits.

As an AMATEUR about automobiles, I put seat belts in the 2-door Plymouth I came out west back in 1956. Bought a kit in 1957, put them in the front seats myself. Did that with my restored Austin-Healey, too. Made SENSE to do so...even though never involved in any collision or 'roll-over.' The 1961 Chevy Impala convertible that followed had seat belts already installed.

Aren't we talking WAY OFF the subject of WIRE STRIPPING here and about times that few of you actually LIVED and EXPERIENCED?

>> On the other hand, I've silvered my telescope mirrors in my garage. This
>> involves a litany of nasty stuff, from Silver nitrate to potassium
>> hydroxide to nitric acid. (now that stuff is scary) And oddly enough,
>> sucrose and citric acid. I'd hate to be not allowed to do such things
>> because someone thought I might get hurt.
>
>Hydroflouric acid is *really* nasty.
>
>The Big Issue IMHO is whether a dangerous process can be made safer.
>Is there a safer way to silver a telescope mirror?

Yes, there is, and it results in a mirror with fewer optical aberrations on its surface. It is deposition of metal (usually aluminum) in a vacuum. My lead-man at EOS, Doug McFarland, was an amateur telescope maker (and licensed radio amateur) and got his mirrors 'silvered' that way for his 6 and 10 inch refractors.

>There *is* a safer way to remove enamel from wire, and you get the
>added bonus of a tinned wire. Why use a chemical at all?

Try stripping some #42 enameled magnet wire made around 1950 by 'solder pot' or abrasive techniques and the end product will not be very good. That old enamel covering will harden with time. CHEMICAL means to loosen the enamel WITHOUT any copper damage is the COMMON SENSE approach to getting an electrical connection. It is fast, inexpensive, and, IF USED WITH APPROPRIATE CAUTION, safe enough in an enivornment that is FULL of MANY DANGERS.

Do you wear thermal-insulating mittens or gloves when handling a soldering iron? YOU SHOULD...IT IS 'GOOD FOR YOU.' Soldering irons operate at tip temperatures high enough to inflict very serior BURNS on the skin.

Do you inhale fumes from rosin flux while soldering? DON'T DO IT, WEAR SELF-CONTAINED BREATHING APPARATUS! 'IT'S GOOD FOR YOU!' Who knows what other FUMES are given off when soldering? Has anyone done 'controlled tests of human dangers' from that? Better hurry up to catch up with the DO-GOODERS!

Do you wear PROTECTIVE GLASSES when drilling wood or metal? BETTER DO THAT! 'IT IS GOOD FOR YOU!' Who knows when you get clumsy and don't hold the work tight and pieces fly off, possibly impacting your precious EYES! Ya gots to have PROTECTIVE EYEGLASSES!

Do you wear self-contained breathing appartus when spraying paint? BETTER DO IT, 'IT IS GOOD FOR YOU!' All that toluene and acetone and other DANGEROUS hydrocarbon compounds are set free and will CONTAMINATE YOU AND THE ENTIRE PLANET!

Do you wear protective gloves when working with sheet metal or any substance that can make a sharp edge that would PIERCE YOUR SKIN? BETTER DO IT, IT IS GOOD FOR YOU! We can't have you in GREAT DANGER from open wound infections!

Oh, oh, oh, THE WORLD IS FULL OF *DANGERS*! Protect yourself from EVERYTHING that might, possibly, maybe damage your precious body...or neighborhood...or city...or the planet. DON'T DO ANYTHING. Just sit at your computer (with non-CRT flat-screen display so you won't be in danger of X-RAYS from those old CRT displays) and make Do-Gooder noises...especially to those of us who spent a lifetime IN the electronics industry.

Keep your 'Southgate Radio' company SAFE.

Perhaps the idea is to eliminate rework and repair. Remember the
slogan "Ending is better than mending"?

> No-lead; a feel-good solution to a non-problem.

I disagree!

I think it's the wrong solution to real problem.

Here in Pennsylvania, there's a "core charge" ($7? might have gone up) if you try to buy a new car battery without an old one to trade in. Besides being an incentive to recycle, it gives the auto-parts folks a chance to put the old battery alongside the new one and make sure it's the right size.

But the main point is this: Not all car batteries are recycled; some do get into the waste stream. The same is true of other lead-acid and ni-cad cells (cadmium is a heavy metal, too). Yet those things are not outlawed. Instead, recycling and education programs are set up to keep the lead, cadmium and acid out of the environment.

IMHO, such recycling for discarded electronics is a better solution
than banning lead-tin solder.

EU doesn't have to. RoHS (Reduction of Hazardous Substances) is an in-country (European) specification that covers a LOT of different substances. In one way RoHS is no different than the FCC specification that forbids MARKETING of receivers than can listen to cellular telephone frequencies...or the way older specification that stated TV sets sold in the USA must be capable of tuning in UHF TV channels...or the FCC specification about linear RF amplifiers that can cover CB that aren't allowed to be sold IN the USA.

RoHS is NOT an international specification. Manufacturers who sell ONLY in the USA and don't care to enter the European (or RoHS-member) markets aren't obliged in any way to obey RoHS standards. USA DoD contracts on electronics can use lead-bearing solders, no problem.

NASA used CONFORMAL COATINGS or encapsulation on spacecraft electronics in the beginning of the 1960s. NOT for any sort of 'tin-whisker' problems but for the fact that microgravity environments all all kinds of small or large junk to float around freely. It MIGHT be that some teeny conductive junk could short out traces on a PCB in space. Hardly likely in an earth environment with gravity all the time. Those same conformal coatings were later found to inhibit the growth of CERTAIN metal whiskers (tin is not the only one). Except for one potting compound allowed back in the 1960s, such coatings and pottings were not epoxoids. The others were closer to offshoots of silicone elastomers and could be reworked.

There are all sorts of coating compounds available now. Emerson & Cuming built their long-running business of providing all kinds of polymer compounds for the electronics industry. Those aren't cheap. No such products are.

"Tin whisker" problems take a LONG time to show up. Usually it takes a half year for the first such whiskers' start to become visible under

100x magnification. Repeated heating-cooling tends to hasten such growth (of a sort of crystaline form of tin) but such studies aren't quite complete yet. But, once started, the growth can accelerate. Even that is not speedy.

Thanks to MARKETING folks, there has been a lot of hysteria about this "tin-whisker" thing generated and picked up by all who have no experience in such things. A conformal coating will inhibt whisker growth. Even an ordinary varnish used on wood surfaces. I'd avoid the green 'solder-mask' stuff found on PCB assemblies which are used to prevent excess solder during wave- and reflow-soldering; it is tough stuff and much harder to remove if put on soldered pads/lands via additional coatings. I'd avoid lacquers because they leave a lot of stubborn ash behind if one MUST 'rework' something...despite their easy application and quick drying time and nice appearance after application.

Seen those in action.  But, be prepared for significant STICKER SHOCK
if you
want to buy one.  Get Eraser's Price List for some knock-yer-socks-off
costs.

Compare that to a $3 bottle of Strip-X from GC two decades ago...which
could last a HOBBYIST for a decade.

This forum is for HOBBYISTS, not manufacturers.  If I want to use
abrasive methods of removing magnet wire coatings, I'll just rip off a
quarter of a small square of emery finishing paper (used in painting
furniture) and use that for a couple of months of intense coil
building.  Costs maybe a dime for that.

=======================================

In the Netherlands and other EU countries all electrical goods are subjected to a 'prepaid removal fee' This variable fee is payable on purchase ,be it an electric toothbrush ,a microwave oven or a TV set ,computer ,printer etc. It means that upon disposal the unit can be taken to any retailer who is obliged to dispose of the equipment in a responsible way(recycle yard)

Also spent alkaline,Nicad,NiMH ,any type of battery can be put in a container at any retailer including supermarkets who are selling these batteries , even if you do not intend to buy batteries at that time.

In the UK they are lagging behind with these measures.

That's close to what I'm talking about. Seems to me that's a better
solution than demanding no lead-containing solder.

> In the UK they are lagging behind with these measures.

Here in the USA, some retailers (Home Depot, Staples, Pep Boys)
have done similar things for batteries, motor oil, printer cartridges,
compact flourescent lamps, cell phones and some other items.
In some cases
it's a government regulation, in others it's a way to get you into
the store, and in others it's just a desire to do the right thing
rather
than being forced to do it.

The idea of building in the disposal cost up-front is a good one,
IMHO, because it reveals the true cost of the item, not just the
immediate cost.

James is correct... that the RF clipping technique is somewhat more
effective. What he fails to mention is that it's more complex... and

not easily installed into an existing radio. RF clipping also
exihibits substantially more distortion. The VoiceMax installs
easily... and provides tangible results.

Xref: g2news1.google.com rec.radio.amateur.homebrew:148

Hi all,

I have documented about 250 of my hamradio (and other)
projects, from antennas, filters, control, transmitters,
receivers, and ...... loads more.

Harry's Homebrew Homepages are to be found at:
http://web.telia.com/~u85920178/
    1) Select subject area (eg. projects), at the top of the screen
    2) select the type of project (TX, TX, PSU, etc).
    3) choose a project from the left panel.

Latest projects are:

DIY Transformers
http://web.telia.com/~u85920178/power/diy_transformers.htm
(G�r-det-sj�lv transformat�rer)
Yes, I have found a source of re-windable transformers, and they are CHEAP.
Here is how you re-wind them.

Diode Switching Basics
http://web.telia.com/~u85920178/data/diode_switching_01.htm

Practical info and ideas using the diode as a switch:
- Signal switch
- Wide-range VCO
- Diode-switched intercom
- RF TX/RX switching

(Currently being translated into Svenska som artikel f�r SSAs tidningen QTC)

Other projects include:

7dB Colinear Antenna for VHF
http://web.telia.com/~u85920178/antennas/7db-colinear.htm
Colinear antenna for 145MHz. 10dB more than my old 1/4-wave.

Alternative power:
http://web.telia.com/~u85920178/power/invert1_00.htm
How to generate high power AC, from 50 Watts to 8kW

Simple receivers.
http://web.telia.com/~u85920178/rx/regen2.htm
Ideal for the novice, or people like me who just love 'em

TV transmitter:
http://web.telia.com/~u85920178/tx/tv_tx_02.htm
One boxer - one TV chanel shared with neighbours
10 neighbours = 10 channels, and still only one box per house
(only illegal to get caught)

Need 6.3vAC + 250vDC for that valve rig?
http://web.telia.com/~u85920178/use/tubepsu.htm
All uses readily available components

Want a valve rig?
TX = http://web.telia.com/~u85920178/tx/2tubetx.htm
RX = http://web.telia.com/~u85920178/rx/tube-rx.htm

Educational:
Synthesiser basics = http://web.telia.com/~u85920178/conv/syn-info.htm
Synthesiser trainer = http://web.telia.com/~u85920178/use/synth-00.htm

Got some EPROMs?
Make ae EPROM burner = http://web.telia.com/~u85920178/eprom/eprom-01.htm
AF Sine generator = http://web.telia.com/~u85920178/eprom/epromosc.htm

R/C Models:
http://web.telia.com/~u85920178/use/rc_enc_02.htm
Analogue cntrol unit, up to 9 proportional channels
(Even via 2m, GSM, 446MHz, 433MHz, etc)

These were just a few examples of the projects available. Currently building a 50pf + 50pf + 50pf variable capacitor for a new HF receiver. Uses PCBs. PCB foil patterns given for most projects at http://web.telia.com/~u85930032/. Sorry, no software for my homebrew computer at http://web.telia.com/~u85920178/use/analcom.htm

I came across Mike Dossor's mosfet hf amp in the 3/99 QST and am interested in using it as part of a mobile psk station. Anyone out there built this? Specifically, I'm looking for substitutes for the heatsink which is apparently no longer available and generally any hints, tips, gotchas... Thanks in advance.

gary

|
|James is correct... that the RF clipping technique is somewhat more
|effective. What he fails to mention is that it's more complex... and
|not easily installed into an existing radio. RF clipping also
|exihibits substantially more distortion. The VoiceMax installs
|easily... and provides tangible results.
|----------------

Actually as easy to design an RF Clipper as an audio compressor. True
it is a bit more difficult to install. Audio clippers can be external
to the transmitter and simpler to install and operate. A RF Clipper
will install as easily as your internal audio compressor.

Personally I would take RF clipping over Audio compression any day
with SSB transmissions. If the post filters are good in enough RF
clipping, there is not significant difference in distortion.

james

Xref: g2news1.google.com rec.radio.amateur.homebrew:155

I've been playing around with some homebrew superhet radios, and I'm finding
that a significant amount of energy ends up at my 1st IF frequency that seems
to be coming from the LO. While I expect to see energy from LO+/-IF end up at
IF, of course, I've checked the LO+/-IF spurs (the LO is coming from a
PLL-based synthesizer), and in general it seems that a lot more energy ends up
at the IF than what the spurs alone would suggest. I remember a talk I
attended where the presenter mention that one of the biggest problems with
building receivers was "the LO getting into the IF," so I'm thinking this is

what he meant? Are there other less obvious paths for the LO getting into the
IF than just the LO+/-IF spurs?

The signal right at the IF eventually gets turned into DC and hence filtered
out, so in theory it doesn't really matter that much, but in practice with
very weak signals eventually the IF feedthru is stronger than the weak
signals, so it limits how much amplification I can provide and hence limits
the ultimate sensitivity of the receiver.

Thanks,
---Joel Koltner

Local-oscillator "blowthrough" is almost inevitable in non-balanced mixers. Even in single- and double-balanced mixers it's fairly common - it's an indication of less-than-perfect balance. Commercial DBMs usually quote an IF-isolation spec. For example, the popular Mini-Circuits SBL-1 mixer seems to have LO-to-IF isolations of anywhere from better than 65 dB (at HF) down to around 30 dB (at UHF). If you're trying to tune a weak signal (say, 80 or 90 dB weaker than the LO signal) then the residual LO feedthrough can cause the sort of swamping you're seeing.

Homebrew DBMs with hand-wound toroids, and less-than-well-matched diode sets may have significantly worse LO-to-IF isolation.

With diode-and-transformer DBMs, performance can degrade significantly if the mixer ports don't "look into" a nice broadband 50-ohm impedance. If, for example, you connect the IF port directly to a bandpass filter, the filter's impedance at the LO frequency is likely to be very much different thatn 50 ohms, and this may affect LO feedthrough.

The higher-performance superhet designs I've seen, generally take care to ensure that each mixer port sees the proper termination impedance. In the case of the LO port, the easiest way is to generate a stronger-than-necessary LO signal (maybe 13 dBm) and then feed it to the mixer through a 50-ohm pad (6 dB in this case).

In the case of the RF and IF ports, you can either use a resistive pad with modest attenuation (perhaps 3 dB), or use a diplexer. For the IF port you might want to feed the mixer into a common-gate or common-base broadband amplifier stage, run at a current level which gives it a 50-ohm input impedance... and then feed the output of this amp to your IF bandpass filter.

I've seen one fairly expensive device (a Tek spectrum analyzer) which had horrendous RF-spur problems. Turns out that its front end uses a simple non-balanced diode mixer with essentially no RF-to-IF or LO-to-IF isolation. The LO-to-IF isolation isn't a problem due to the nature of the analyzer design... but the analyzer uses a relatively low swept-IF frequency range, and the incoming RF signals can blow right through and be detected as if they were IF mixing products. It's an OK analyzer for bench testing of many radios, but is pretty much useless for trying to look at VHF over-the-air signals.

```

Screening is the best solution. Put the various stages in separate
screened enclosures.

Leon

But I was under the impression that RF clippers only work on SSB?...
and the installation involves tearing into the IF section?

Before writing my comments, I read the comments of two others who
responded to your query.

On Wed, 11 Jun 2008, Joel Koltner wrote:

> I've been playing around with some homebrew superhet radios, and I'm finding
> that a significant amount of energy ends up at my 1st IF frequency that seems
> to be coming from the LO.

At this point I'd like to know what your problem is with "significant
amount of energy..." compared to whatever your ultimate goal is.

While I expect to see energy from LO+/-IF end up at
> IF, of course, I've checked the LO+/-IF spurs (the LO is coming from a
> PLL-based synthesizer), and in general it seems that a lot more energy ends up
> at the IF than what the spurs alone would suggest.

Again, what specifically are you "seeing" (measuring?) compared to what
you think you should be getting? Could your PLL synthesizer be dirtier
than you think?

I remember a talk I
> attended where the presenter mention that one of the biggest problems with
> building receivers was "the LO getting into the IF," so I'm thinking this is
> what he meant? Are there other less obvious paths for the LO getting into the
> IF than just the LO+/-IF spurs?

One way I would think about this is to ask if you looked at known circuits
that work and ask yourself what are you doing that is different from known
circuits that work. We also had some posts maybe 1-2 years ago where a guy
was working with chips and circuits and computer modelling (IIRC) and he
was unhappy that he was not getting (with real circuits) what his computer
modeling program told him he was supposed to get.

> The signal right at the IF eventually gets turned into DC and hence filtered
> out, so in theory it doesn't really matter that much, but in practice with

> signals, so it limits how much amplification I can provide and hence limits
> the ultimate sensitivity of the receiver.

I do homebrew but with tubes and can tell many stories about what should
have been a straightforward project but electrical performance was
unacceptable. QST has had, in the past, articles on why ham-built copies
of ARRL circuits don't work and of course all the blame goes on the ham
and not ARRL but there is a lot of missing information in the handbooks,
too. I've learned a few tricks by the crash-and-burn, smoke tests with
smoke and no function, the "guess and pray" techniques, and the "dumb
looks"-after-the-smoke response. Very roughly, I'd say 50% of my projects
work the way I hoped they would work, the rest go to the glue factory.

Hi Dave,

Thanks for the information; it's quite helpful!

I was (am) committing the faux pas of feeding the mixer output directly into a narrow bandpass filter...

> For example, the popular
> Mini-Circuits SBL-1 mixer seems to have LO-to-IF isolations of
> anywhere from better than 65 dB (at HF) down to around 30 dB (at UHF).
> If you're trying to tune a weak signal (say, 80 or 90 dB weaker than
> the LO signal) then the residual LO feedthrough can cause the sort of
> swamping you're seeing.

So... say I'm using a 45MHz IF, trying to tune 414MHz using the SBL-1 and an LO of 414-45=369MHz (low-side injection) at the SBL-1's recommended +7dBm. Presumably I'll see a 7dBm - 30dB (LO-IF isolation) = -23dBm signal at the IF, but it should still be at 369MHz, right? How does the LO "bleed through" to the 45MHz IF... and what power level should I expect to see there?

"A" <arthures@panix.com> wrote in message news:Pine.NEB.4.64.0806111740380.7962@panix3.panix.com...

> At this point I'd like to know what your problem is with "significant amount of energy..." compared to whatever your ultimate goal is.

I'll get something in the ballpark of an -90dBm spur at the IF when the noise floor is down around, say, -120dBm. Hence I have a harder time recovering signals at, say, -100dBm even though they still have a decent SNR (and my commercial receives have no difficulty at all hearing them). This is measured on an Agilent 8563 spectrum analyzer.

> Could your PLL synthesizer be dirtier than you think?

I've done some wideband sweeps of it, and there are some spurs that are only ~ -70dBc. It's obvious when you choose a channel that suffers from these higher-level spurs, though... it'll add 20dB or more to the IF spur. I ditched my homebrew PLL-based synthesizer for a good HP box borrowed for testing, though (its spurs are more like -90dBc worst case), and the problem is still there.

> One way I would think about this is to ask if you looked at known circuits that work and ask yourself what are you doing that is different from known circuits that work.

The usual problem is that very few circuits found on the Internet actually come with performance data -- unless you build them yourself, you really have no way to know if they're just as bad or worse than your own efforts!

> We also had some posts maybe 1-2 years ago where a guy was working with chips and circuits and computer modelling (IIRC) and he was unhappy that he was not getting (with real circuits) what his computer modeling program told him he was supposed to get.

```
It would almost be alarming if those circuits did work, in real life, within,
say, 0.1dB of their simulated results rather than the more typical 1-5dB
that's often still considered "good agreement!"

DBMs should be terminated in 50 ohms over a wide bandwidth. MCL has
recommendations concerning this.

I sure hope some Time-Warner subscribers institute a class action lawsuit against them for taking away a big part of the internet for their customers.

|--------------

Correct. An RF clipper an be inserted after the SSB filters or before.
There are versions that do the clipping after the balance modualtor
and before filters. Sherwood did a RF clipper for the Drake TR4 that
was after the SSB filters and had crystal filters to restore the
original bandwidth.

Generally RF clipping is a bit more expensive than audio compression.
Then you get what you pay for.

james

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday June 15th 2008
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and

$15 for each additional at the gate.

The flea will be held on Albany between Mass Ave and Main streets in Cambridge; right in the Kendall Square area from 9AM to 2PM, with sellers set-up time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which offers a 30% discount. By prepaying you get a discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered well illuminated tailgate area is available for all sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776 (M-F 9-5)

********** $1 buyers discount with hard copy of this notice ************

It's very likely that customers will find that nowhere in their subscription contract is access to a Usenet server actually promised... with most ISPs it's been a "free perk" for a long time (years) now.

There was a time when some ISPs provided shell accounts as well -- that's been gone for years as well... although web hosting companies often still provide it.

I thought that there were some stand-alone RF clippers. Surely there is
no reason why they cannot be external units, inserted in-line between
the mic and the mic socket (ie audio in - audio out)?

Obviously they have to contain 'all the works' (oscillator, balanced
modulator, compressor, clipper, filters, balanced demodulator etc), but
at least they are self-contained and universal.

Regarding filtering, the main advantage of RF clippers is that they
eliminate the effects of second-order distortion, and only have the
distortion produced by in-band third order intermodulation. For
cheapness and simplicity, if you leave out the SSB filtering (ie do
everything at DSB), you will have at least twice the number of in-band
IM products. But how much worse is this than having SSB filtering?

At least Datong made a stand-alone unit. There was an article about
RF-clipping and the Datong unit in Wireless World a few decades ago.

Huh? How can you do RF clipping outside the unit? Not a chance...
Any unit that's inserted in the mic jack is no RF clipper.

As I said. "Obviously they have to contain 'all the works' (oscillator,
balanced modulator, compressor, clipper, filters, balanced demodulator
etc)."

And, as Paul said, "At least Datong made a stand-alone unit. There was
an article about RF-clipping and the Datong unit in Wireless World a few
decades ago."

But maybe Datong didn't know what they were doing.

They had a lot of company, and the residents here have a very short memory. Datong was second. Comdel made an RF clipper in the late 60's and early 70's. Mike input and amplifier, mixed up to 455 KHz, sideband generated, clipped the hell out of it, filtered it with a second filter, mixed back down to audio with the same LO for injection to your mike input jack. Every serious contester and DXer had one. Cost more than the receiver.

Ah - here you hit something on the head. I didn't know you were asking
about UHF, but now I can contribute!

SBL-1 balance isolation gets substantially worse as you move from HF
to VHF to UHF. Looking at the spec sheet, as you move from 3MHz (where
I use the SBL-1) to 369 MHz (where you use the SBL-1) the isolation
gets 34 dB worse.

AND the typical and guaranteed numbers are only if all the ports are
terminated nicely.

So while my gut feeling was originally "LO-IF isolation, that's never
been a problem for me at 3.5 or 7 MHz with the SBL-1" now I look at
the spec sheet and think "wow, isolation is a much bigger problem at
UHF than anything I've ever dealt with in the SBL-1 at HF"!

If you can arrange the IF stuff at the output of the mixer such that
you have a good flat termination match and such that you hit an IF
filter that will get rid of the LO before any substantial gain, I
think you'll come out way ahead of just switching to a different
variety of mixer.

Yes, a quick Google on "RF clipper"+Datong brings up lots of info -
about Datong and lots of others. This is one of the first:

Highly recommedned:         http://individual.net/

I've been with them for nearly ten years now.  That's two lifetimes in
internet years.  It's just 10 Euros per year and they have a pretty good
track record on killing most spam.  No binaries, tho'

That sounds very complex and expensive all right.
Another problem I see is that they only work on SSB.
My customers insist on something small that fits inside the radio and
processes in all modes. The VoiceMax does that with less than 1% THD.
Can't build them fast enough to keep them in stock...

Please don't recommend this one; it is plagued with forgers
and spammers and has chosen to block groups like sci.electronics.repair
instead of policing its users.

Why do you think that they only work on SSB? Stand-alone RF clippers
like the Datong are independent of transmit mode. They are audio in -
audio out (with a bit of RF magic in between). They should work even on
an audio PA system.

LOL... a unit like that (http://www.nu9n.com/deq2496.html) would cost
you at least $300. That's more than your whole station is worth!
Come on... you know how frugal hams & cbers are. Get real.

>the 45MHz IF... and what power level should I expect to see there?

I'd say that you could be seeing the 369 MHz LO signal in your IF pathway through a number of mechanisms.

First: some of it may be getting past your bandpass filter. If you're using a crystal filter, you may find (if you look) that the filter's stopband attenuation is neither wonderful nor flat at some frequencies. Crystals often have secondary resonances at (or near) the harmonics of their fundamental frequency - that's how overtone filters work - and your LO of 369 MHz isn't all that far from the 8th harmonic of your IF frequency.

You'd probably need to sweep your filter's response (wideband oscillator plus an RF detector or a spectrum analyzer) to determine if this is occurring.

If this is the problem, you might remedy it by adding a one- or two-stage passive lowpass filter (maybe LC, maybe just RC) somewhere after the mixer and before the final detector. This would attenuate out the residual LO signal that the bandpass filter doesn't. Maybe run the mixer output into that grounded-base/source 50-ohm buffer amp I suggested, gain a few dB, and then run the signal into a slightly lossy low-pass filter whose output presents your bandpass filter with the termination impedance it expects?

Second: you may be getting parasitic transmission of the LO signal *around* the bandpass filter - either capacitive or inductive. If your bandpass filter is a tuned LC type rather than a crystal filter, there might be coupling between the inductors.

Third: you might be getting some LO pickup by the gain stages in the IF path, direct from the local oscillator - wire-to-wire coupling or something like that.

Fourth: you might be getting LO wandering around on the power supply
lines or in the ground paths/planes - insufficient power-supply
decoupling, shared power-supply wires, shared ground paths, and so
forth.

I get the impression that careful attention to layout, shielding, and
decoupling are very important for higher-performance receivers. Some
builders seem to prefer to place the LO, mixer, and filter in separate
shielded sub-compartments (soldered together from double-sided PC
board material if nothing else), to carry the signals between these
compartments on shielded coax, and to use feedthrough caps and ferrite
beads on the power wiring. This helps minimize the various forms of
parasitic coupling between stages.

I don't recall what the guy was upset about. I don't think (IIRC) that we
had any comments regarding what, quantitatively, he was looking for vs.
what he was getting, quantitatively, but he was definitely upset.

I don't have anything like the fancy gear you have and my criteria are more or less "if you can hear it and its OK with you, then its fine" (for receivers anyway). On transmit, I have enough tuned circuits in various places that my spurious signals should be good enough for the FCC. And, I'm using quite clean free running oscillators at VFO, LO points. Its really wonderful to be able to see sine waves on any one of my three Tektronixs scopes, thought. I'll add that if I don't have at least some minimum number of tuned circuits, that "sine wave" develops very visible "distortions." Maybe someday I'll be interested in quantitating them.

In the meantime, good luck on your endeavors. And, thanks for the fills on the technical stuff. Can't help you any more than that.

Looking for #20 teflon wire and of course need only a short length.

Anyone out there have a favorite wire distributor who takes pity on us
homebrew types and sells by the foot?? Thanks all.

gary

If you could get by with a smaller wire, like AWG 24 or so, you can find loads
of that stuff in Cat-5 cable. Just strip off the outer jacket and untwist the
pairs. Pretty cheap too. Don't know the voltage rating of the individual wires,

though.
Alltronics (http://www.alltronics.com) sells by the foot, although they have a 25 ft minimum. Seems the only color they have in stock is red.
Surplus Sales (http://www.surplussales.com/wire-cable/Wire4.html) has it in stock. again, 25 ft minimum.
Action Electronics seems to have the best color selection (http://www.action-electronics.com/ntehuwt.htm#20)
Amp Builders Parts (http://ampbuildersparts.com/store/index.php?main_page=index&cPath=34) also... 100 ft spools, but better price.

Hope you can find what you need from one of those links.

Cheers!!!!

I have plenty of #22 stranded teflon wire if this will work for you.  I
have black and white.  How much do you need?  It's yours for the asking
if you only need something like 20 or 25 feet or so.  Send me a postal
address or callsign I can look up in qrz.com and I send you some if you
can use it.  acepilot at bloomer dot net.

What color do you need? I have some short lengths in stock
of various colors, including some striped stuff. Give me an
address and I'll send you some for the price of the postage.
I'm not sure it is exactly 20 gauge, but it is stranded and darn
close to that size.

Let me know. My email is radioconnection (at) juno (dot) com.
I'll get it out to you if you wish. Send back the postage if you're
happy afterwards.

Pete k1zjh

Question: Why teflon. Heat rating? Or high voltage insulation rating?
Just curious and willing to learn something! TIA terry

Thanks Dave -- great post.  I think I need to take the tiny little ball of
mixer/filter I have, spread it out a bit, terminate all the ports properly,
and start making some measurements before connecting the IF filter, etc. back
up a piece at a time!

I'm in a very fortuitous position, being somewhat a novice at RF design personally, but working at a company that's been doing it for years so I have access to a fair amount of nice test equipment. :-) Sometimes it's a little weird, though -- until a couple of years ago now we had network analyzers going to 6GHz but no scope better than 100MHz!

I think projects like the TAPR VNA (http://www.tapr.org/kits_vna.html -- now sold by Ten-Tec) are great, although it's unfortunate that it tops out at

100MHz, as in many cases one can "get by" with a lot less down at HF or even 2m than those trying to homebrew 70cm or higher gear. Even getting, say, 1GHz spectrum analyzers with tracking generators is not at all cheap (meaning, within most hobbyist's budgets, which I'd say is something $1k or less for such a device) -- there's been discussion on and off for ages on how such a tool would sell like hotcakes, given how much it would benefit homebrewers and commercial users. I kick around the idea of trying to build something like that myself, but I do already have enough experience to know that there's a very large investment in time between "design looks good on paper" and "design actually works" if you're shooting for decent dynamic ranges and resolution bandwidths.

Thanks for your input,
---Joel

Hahaha... but that logic, they're going to have to quit providing internet connections completely! I have no idea what the numbers are, but I suspect that a lot more child porn traverses HTTP than NTTP any day...

There are a number of guys on E-bay who sell short (5, 10, 50 ft) lengths of teflon hookup wire, usually the good silver-plated stranded stuff (although some oddball types like solid silver occasionally show up too!). Their main market seems to be audiophile amp builders.

CAT5E teflon wire has 24AWG conductors.

McMaster-Carr will sell you teflon tubing (no wire inside) by the foot. Add your own wire!

Tim.

Just curious... does anyone know what sort of architecture you find in your typical HT or mobile "receives everything from 100kHz - 1.3GHz!" radio to generate such a vast range of frequencies while still keeping the prices so low (plenty are available for <$200, and I can't expect the LO makes up a particularly large percentage of that total price)? I would tend to lean towards something PLL-based given the typically channelized nature of available frequencies, but a single PLL would still need a VCO with a huge tuning range. So... perhaps a pair of mixed PLLs, with one doing the fine tuning and another the coarse tuning (having been multiplied up from a low frequency)?

I attempted to decipher the schematic included with my Yaesu FTM-10R, but everything is so tiny it was rather hopeless!

I don't suppose any of the reviews ever go through and sweep the LOs while watching for the worst case spur conditions, do they?

---Joel

All they have to do is to subscribe to a commercial news account
and they will have access to everything they had before, and more.

Solution for LO maybe is DDS.
The practical solution of DDS is is extremely simple and cheap.
Please google word "DDS"

> Just curious... does anyone know what sort of architecture you find in your typical HT or mobile "receives everything from 100kHz - 1.3GHz!" radio to generate such a vast range of frequencies while still keeping the prices so low (plenty are available for <$200, and I can't expect the LO makes up a particularly large percentage of that total price)? I would tend to lean towards something PLL-based given the typically channelized nature of available frequencies, but a single PLL would still need a VCO with a huge tuning range. So... perhaps a pair of mixed PLLs, with one doing the fine tuning and another the coarse tuning (having been multiplied up from a low frequency)?

I suspect that they first upconvert to somewhat higher than the 1.3GHz upper frequency limit, then use a roofing filter with however many itty bitty IFs it takes to get back down to a reasonable bandpass filter.

I also suspect that the receiver receives everything kinda well, not superlatively.

> Solution for LO maybe is DDS.

That's a big "maybe" -- even the fastest DDSes aren't much better than 1GSps or thereabouts, giving a realistic tuning range of 0-400MHz... and those parts are quite power hungry and not at all cheap (e.g., Analog Devices' AD9858 is several watts and nearly $50 even in quantities of 1000!). On the other hand, one of the much lower frequency DDSes in conjunction with a mixer would probably work well -- although it just shifts the problem to how to get nice and pure, very wide range fixed frequencies to mix with. (E.g., DDS does 0-200MHz, so now you need just, say, a 200MHz+/-IF, 400MHz+/-IF, 600MHz+/-IF, etc. oscillators to mix with...)

Of course with the very fine-grained frequency resolution of a DDS, multiplying the output up would seem to be an obvious approach, but I'm told this isn't typically used due to the relatively high spur levels of the DDS itself.

Sure, I use Forte for all of $2.95 per month (http://www.forteinc.com/apn/index.php), and I've never come *close* to the 10GB/month transfer limit, although of course I'm not downloading warez nor kiddie porn!

I can see people being upset with Time-Warner's decision, though -- effectively it does translate into a rate hike.

The HT-class wideband receivers typically will have a first IF in the
45 or 70 MHz range, and use a number of different PLL's one for each
different band. Each PLL is literally less than a square cm on the
PCB, and there's a lot of them.

At least one Sony from the mid 90's had a 10.7MHz second IF, and if the frequency you wanted was anywhere near the first IF of 70MHz, then they skipped the first IF and went straight to the second IF.

For FM the 10.7MHz IF is the ending point... for non-WBFM modes there was a third IF of 455kc with some ceramic filters.

Some of the HT's have 5kHz channel spacing on the HF band with no finer tuning available (OK for SWLing but nothing else), but the slightly better ones have finer tuning in the HF range thanks to a the 2nd or 3rd LO being a PLL too.

Image rejection is nearly completely nonexistent.

Tim.

Howdy, Folks,

I recently released a freeware Win98/2000/XP/Vista program that generates codewheel images and prints them to any home inkjet or laser printer.

With a good codewheel in hand, you can build your own optical encoder.

I tried to generalize the program with six "canned" wheel types, plus a user-defined wheel type that lets you design a codewheel for just about any application you can imagine.

The program can generate wheels from one to eight tracks, at user-specified size and resolution.

My favorite feature is its automatic 1:1, no hassle printing. Want a 2" diameter wheel? Set it for 2" outside diameter, and the wheel image will automatically print at 2" diameter. No muss, no fuss.

You can spec the wheel image's resolution to anything practical. If you have access to better printers than you might find at home, or want to produce your wheels via photolithography, you can export the image as a .BMP file, as either a positive or negative image.

And did I mention that it's free? It's so free that I don't even have any advertising on my web page.

Speaking of my web page, I think I should probably tell you where to find it:

   http://www.mindspring.com/~tom2000/Delphi/Codewheel.html

```
Very 73,

   Tom  AB9B

True... the most common color for Beldsol-type stuff seems to be the
```

dark red. But I think some (most?) green is Beldsol-type too.

If it doesn't vaporize in solder, I usually just go at it with sandpaper.

Tim.

Some of the magnet wire I have will do that, some won't, and some needs
to be scraped a bit with a knife before it works -- the heat will kill
the adhesion between wire and enamel, but it won't do in the enamel.

I generally always scrape with a knife, then tin -- but I wouldn't put
anything I build through a vibe test!

General Cement's "Strip-X" hasn't been sold by them for at least a dozen years. I sent them a letter some time ago, got a nice reply to that effect from a female-named staffer "who had not worked for them before that." :-)   Their home office is also my home town. :-)

"Strip-X" worked like a charm. For decades as an over-the-counter product. Nothing over-the-counter now works as well as it did from 1948 onwards to whenever they stopped repackaging it. Note: GC did a lot of repackaging of bulk material and tools as well as some manufacturing. GC went through a series of corporate restructures, buys, and buy-outs, just aren't the same company as when I left Rockford, IL, in 1956.

As a fellow professional, I've tried to find out what other manufacturers use. Most use a mechanical "stripper" that abrades coatings...but quite expensive, too much for the average hobbyist. At least one "makes their own" but is very close-mouthed on what their "own formula" is...:-)

>One poster in an earlier thread stated that it was designed to work with Formvar insulation, and might not work as well on the newer Polythermaleze insulation.

The only problems I've ever had with "Strip-X" was with some surplus Teflon-coated (!) magnet wire obtained decades ago. But, my last bottle of "Strip-X" dried solid about 8 years ago.

>There's a paint-and-finish stripper of a similar name (Klean-Strip Strip-X) available these days. Like the wire-"Strip-X" it contains methylene chloride, but it has no cresol or ammonia. Its other ingredients include toluene, xylene, and methanol, plus a thickener (it's relatively goopy and would probably have to be wiped off of the wire using a paper towel or Q-tip or something like that).

I've tried to find one out of three different brands tested, from Lowes, Home Depot, OSH (Orchard Supply Hardware), and Do-It Centers. They remove oil-based paints with difficulty and aren't even close to "Strip-X" for magnet wire, any coating. Roughly a $60 experiment in trying for a substitute all of which were unsuccessful. Bummer.

>These chemicals all come with fire- and health-hazard warnings... if you use 'em, do so with proper care and precautions!

The do-gooders done did too much with all those warnings and attempts to protect us all from everything. :-(I'd only been using Strip-X since 1947 and known lots and lots of folks who stripped magnet wire using Strip-X. No "fires" caused by the stuff and most of those I knew did not suffer from any "health-hazards" inhaling (very briefly) the stinky odor from Strip-X. It's sort of like anything with an odor should have "Caution: Breathing will eventually result in death!" warnings.

At one time (just about 8 years ago), pure acetone was VERY hard to get in pint/quart containers. It is an excellent solvent for lacquers, brush-cleaning, etc. (not good for wire stripping though). As of about 3 years ago it and a few other aromatic hydrocarbons started appearing in do-it-yourself stores. Maybe there's some relaxation in all those dire predictions, warnings, etc., etc., etc.

My late father-in-law was a polymer chemist. He died in 1977 so can't help me. I just hope that some chemist could come to the aid of us hobbyists using coated magnet wire and provide us with a GOOD product like Strip-X was. Meanwhile, it's back to being VERY careful with a sharp X-Acto knofe and scraping coatings. With #34 AWG that requires Zen-like calmness...

Here's a link to the "Material Safety Data Sheet" for Strip-X which
shows its components with % by weight of each.

http://www2.itap.purdue.edu/msds/docs/1451.pdf

[67% methylene chloride, 17% phenol, 4% ammonia, 20% inert thickeners]

It's probably due to the paint stripper we've been inhaling for all those years. Out of all the possible ingredients, I'm blaming it on the thickener.

=======================================
The (potential health)problem chemicals are the C6H6-ring hydrocarbons
: toluene and xylene .

In addition to breathing the vapours , skin contact with the liquid is
outright dangerous
Most products containing these benzene/benzol derivatives are no longer
available to the public at large ,since they can cause cancer.
But.......they are very effective solvents.

Naaa, it's the people who think they should be rewarded for stupidity
and basic capitalism that took all that stuff off the market. Some
idiot did something stupid with the product and decided to sue. The
company looked at a long legal fight or settlement and settled. They
looked at a couple settlements and decided it would be more profitable
to eliminate the product and concentrate on other things as they're not
in the business to keep consumers satisfied, just get their money and
keep as much of it as possible.

If a product is dangerous, why shouldn't it have warnings?
Particularly when
there are known carcinogens and other health hazards involved?

It's not being a "do-gooder" or "doing too much" to discover hazards
and
eliminate or contain them.

Sure, not everyone who uses Strip-X will get cancer. But some of the
components of it are known carcinogens, and a proven hazard. More
important,
we can't know ahead of time who the susceptible folks are.
>

Maybe. But I doubt it.

More likely, they looked at the *possibility* of such a lawsuit, the
scientific
evidence of the hazards of the ingredients, the limited profit and
declining
sales, and just stopped making the product.

Once a chemical is shown to be dangerous, the manufacturers can't
claim
ignorance anymore.

> They...decided it would be more profitable
> to eliminate the product and concentrate on other things as they're not

Profitability is what "capitalism" and "business" are all about.
Without
profitability, a capitalist company just disappears.

Since the formula for Strip-X appears to be in the public domain,
anybody
can make it and sell it. Would *you* be willing to set up shop to make
it
and sell it, with all the risks that entails, and the very limited
market for it?

I've always burned off the insulation with a lighter, removed the
remaining ash with a couple swipes of very fine sandpaper, and
tinned.  Never had a problem yet.

Mike

===================================
And (quite rightly)the FDA , EPA and other relevant agencies at Federal
and State level will be taking action .

In Europe action against dangerous substances is nowadays increasingly
taken through legislation by the European Parliament. I welcome that

That's what I've always done, too, but the last time I suggested it,
all I heard were lots of complaints about how much easier it was to
spend a lot of time breathing odd fumes.

Yes, there certainly was a commercial product once sold for this
purpose, but I suspect the only reason it was out there was because
they knew they couldn't make much money selling "Wire Stripper Kits"

that consisted of a book of matches.

;-)

Really Scott, if it hasn't tinned after 20 years, it probably isn't
going to... hehe, sorry, couldn't help myself! ;^)

I wonder if items such as Strip-X became obsolete due to changes in
insulation composition, i.e. not working on new types of insulation. But
I do agree about the folk who would protect us from ourselves. Strip-X
was pretty innocuous stuff.

Did you by any chance try some old style enameled wire in your
experiment above?

The acetone issue is a strange one. Acetone is one of the safer
solvents out there, heck our body even produces some acetone. Aside from
the obvious precautions for flammable materials, the biggest problem
with it is for people who wear contact lenses of the plastic variety.

Splash some in your eye, and if it gets to the edge of the contact,
capillary action will suck it under the lens, and weld the contact to
your eye. Removal effectively blinds the person. Otherwise it's pretty
safe stuff. I just don't wear contacts - even under safety goggles -
when I use it.

That is an understatement1 8^) I have to make sure I am in a good mood,
and no coffee for me that day before I attempt that sort of thing.

I think it a matter of magnitude.

Some items such as Benzene are pretty dangerous and have an established
track record of making people sick. Those should go whenever possible.

OTOH, the little bottle of Strip-X with it's foul stench is probably not
going to cause anyone harm outside of self inflicted (i.e. suicide attempts)

Of course, I'm not so sure if Strip-X was discontinued because of health
concerns or that it just didn't work any more on new generations of
enameled wire.

There you touch on the real issue with items like Strip-X. The manufacturing side. While I might have my little bottle that I get out a time or two during the day, the people making the stuff have exposure issues well beyond that.

As an aside:

The butter flavor on your popcorn (diacetyl) has a nasty side effect for the people who make it (and apparently at least one microwave popcorn addict) when it vaporizes, it can pretty seriously impair lung function. It is a natural substance, but the way in which it is used is the problem

http://en.wikipedia.org/wiki/Diacetyl

http://www.butterflavoringlunginjury.com/index.htm

http://defendingscience.org/Diacetyl-Background.cfm

But I digress. My main point is that while we might not get much exposure, those who produce it just might be getting serious contact with nasty chemicals.

Does some one have a diagram of the tube locations for a Breting 14? I would appreciate saving the time of ferreting out the schematic against the sockets.

Thanks,
Paul P.

Hello everyone,

Regarding Astron Power Supplies, repair, retrofit, information and modifications of the supply hardware and replacement Regulator Boards.

There are/were a number of different Astron Power Supply Regulator Board versions made and configured. What is placed on the specific board is related to it's capacity and type of operation. Depending on the year of production, the size and the series the boards can and do change a bit. Here's the url for the Repeater Builder web page,which has a lot of good information:

http://www.repeater-builder.com/astron/astron-index.html

In some of the online yahoo groups I've mentioned some of the short falls of the original Astron Circuit design and how I dealt with them. Since that time I started selling replacment regulator boards with updates and related information.

I offer a complete updated Astron Regulator board package, which is the populated board and instruction sheet. The package also contains my notes, information and various circuit diagrams. The price is $45 plus the cost or US Priority Mail (about $4.35)

When your original Astron Board becomes problematic... my drop in replacement is an updated clone of the original board with modern improvements. Indeed Astron has included some of the mentioned improvements onto some of their current regulator boards (but not all). I've also addressed the fairly problematic crow-bar circuit layout and part values to make the retrofit regulator board more stable. I've never had one fail...

The variable supply is the same type board with part modifications to allow adjustment of the output voltage within a practical range. The ability to convert your specific supply to variable control is probably more dependent on the date of mfgr of your regulator and the version of your board. I have a list of each original Astron Regulator Board part value based on size and the values on my replacement boards. If you've charcoaled a part value I can supply the value information.

By Email and telephone I'm happy to help you trouble shoot your supply, regardless of the mfgr. But my time is limited and I might not get back to you right away so please be patient.

cheers,
skipp

A number of gremlins cause the crow-bar to mis-fire. Just depends on
your specific regulator board version and part values used. One of the
reasons I came up with my replacment regulator board option.

http://www.repeater-builder.com/astron/astron-index.html

I've not seen a newer generation crow-bar circuit fail causing
equipment damage.. but as always your results might vary.

cheers,
s.

Re: Astron Power Supply Crow-bar Circuit Operation

:> I'm wondering how many others of you have seen defective operation,
:> sooner or later, or other deterioration in your high current regulated
:> DC supplies?

Happens more with the older supplies... part values change with time.

: However operation of a crowbar should blow a fuse fitted 'upstream' of
: the pass transistors.   As already explained earlier in this thread ,the
: crowbar should also be fitted 'upstream the pass transistors (but
: 'downstream' the fuse , while sensing the output voltage .

I don't agree...

: If the Astron voltage regulator would be suspect I would recommend a
: very simple circuit with a 7812 voltage regulator and a PNP transistor
: ,its output 'steering' the pass transistors .
: Ref : Experimental Methods in RF Design , by W7ZOI-KK7B- W7PUA
: page 1.15

Not a good idea... regulation really suffers bad.

: Instead of the 3 legged 7812 you can also use the similar LM317
: enabling output voltage adjustment
: After all this is a homebrew NG

No good... if you're only trying to get in the ball park maybe... if
you plan to use and trust the supply with expensive equipment you should
stick with an LM-723 or similar circuit properly designed using the mfgrs
data sheet information.

cheers,
skipp

: The diagram looks strange to me, with a direct connection from the
: higher voltage driver supply (e.g. pin 12 of the 723 or collector of
: Q2) to the base of the series pass transistors.

The pass transistor pre-drive transistor is a simple current amplifier.

: With a higher separate driver power supply the driver current should
: flow through the Q2 driver transistor, through the small resistors
: into the base connection of the series pass transistor. Thus in the
: diagram the direct connection from the driver supply to the series
: pass transistor base should be removed.

Some of the available circuit diagrams have mistakes...

:>I modded one of those significantly. Too long ago to remember the exact
:>thing I did, but DO put that crowbar SCR anode on the collector of the
:>pass transistors. If it trips as is, you kiss the current meter and
:>expensive current sense resistor goodbye.

: When using crowbars, there should be a some kind of fuse on the
: feeding side, preferably immediately after the filter capacitor.

No, you want the entire supply to remove itself from operation if
the crow-bar circuit fires.

: If the crowbar is before the series pass transistors, it is a good
: idea to put a large reverse biased diode across the series transistors
: (CR7 in the diagram), which would discharge any large capacitors on
: the regulated side through the crowbar. Without the diode, the
: collector side would be at 0 V after the crowbar tripped, but the
: emitters could still be at +12 V due to any large capacitors on the
: regulated side.

An expensive part... the crow-bar is best left at the tail end of the
supply (where it is now).

cheers,
s.

Amen Paul,

The Astron 25 amp variable supply is pretty much the parts for the higher rated supply in the same case. The no free lunch rule applies. If you modify your specific supply for varilable control... it will quickly become to hot at lower voltage - higher current values.

cheers,
s.

You're right about the schematic in the link above. There is an error in the drawing. The wire between the collector of Q2 and the bases of the pass transistors Q101 and Q102 should not be there. That connection would put full rectifier output on the bases of the pass transistors, turning them fully on, resulting in the PS output going way high with no regulation. Maybe even destroying the pass transistors.

However, the link is to a schematic for a RS-35, not an RS-20. The OP has an RS-20, and the proper schematic link should be
http://www.repeater-builder.com/astron/pix/astron-rs20-1988-09-23.gif.

>>I modded one of those significantly. Too long ago to remember the exact
>>thing I did, but DO put that crowbar SCR anode on the collector of the
>>pass transistors. If it trips as is, you kiss the current meter and
>>expensive current sense resistor goodbye.

Remember that the purpose of the crowbar is to protect the load from power supply overvoltage, not to protect the power supply. The crowbar should be connected to the regulator output, not the input. If connected to the input, the reservoir capacitor(s) on the output are still charged when the crowbar fires, and the overvoltage condition is applied to the load until the capacitors drain. The load is unprotected.

Remember also that most of the Astron supplies have current foldback limiting. That means that on a shorted output condition, the regulator should reduce the available current into the short to a significantly lower level, protecting the pass elements and regulator.

I have a number of 6146s that I know I'll never use in the future and would like to sell them to someone who will, or wants spares.

All used, many known to be good from prior use or users. Couple in original boxes. Might be one 6146a, one 6146w. If this is important, let me know.

$3.00 money order per each, plus postage (USPS).

$2.50 each for all to one buyer.

Respond to the given email address associated with this post (its live but has spam assasin set up so don't talk too much commercialism or it might get bombed to /dev/null). If I don't respond in a day, then make a post responding to this and give your munged email address and I'll get back to you.

Just put a reverse biased diode across the series pass transistors.
When the crowbar at the main capacitor fires, the output capacitor
will be discharged through that diode and crowbar, protecting the
load.

>

Foldback limiting requires that the differential amplifier (in the

723), driver and series pass transistors are working properly, thus,
the crowbar+foldback limiting works properly only if the 723 reference
voltage is erratic. In all other failure modes, such as dead 723,
shorts in driver or series pass transistors, it is quite unlikely that
the foldback would work as expected, if the crowbar fires due to
output overvoltage.

I would invite you to join the Yahoo rfamplifiers group and ask the
question over there.

http://groups.yahoo.com/group/rfamplifiers

cheers,
s.

: Richard <nearlynews_email@ntlworld.com> wrote:
: I need some information on an appropriate input circuit for a small RF power
: amplifier using a 2E26 operating in the HF region. Output would be about 27
: watts. Drive input power about 0.12 watts.

: I want the input circuit of the PA to present a 50 or 75 Ohm load to the
: driver (the exciter - probably a CW QRP rig - will supply about 0.12
: watts). Perhaps (I muse) it would be good, (certainly it would be
: convenient) if the input circuit was NOT a tuned input circuit, but see
: below.

: Questions (that incidentally show my thinking):

: Can anyone point me to a website that gives the design data for an
: appropriate circuit given the things I have mentioned?

: Is it okay to have an untuned grid circuit? I muse no problem if the
: exciter has a pi-network output circuit. I just wonder that if the exciter
: uses a pi network, if that would represent both the exciter anode/collector
: tank circuit, and the grid tank circuit. (So, really there would be a tuned
: input circuit - the output pi-network of the exciter). (Just shows I know
: nothin', I'm not even certain whether solid stage rigs use Pi-networks to
: match with the load).

: Any thoughts on biasing arrangement - fixed bias, drive bias, or cathode
: bias? (Perhaps fixed bias is best - no need for a clamp valve). Grid bias
: needs to be about - 45 volts. Muse that a simple RF choke supplying the bias
: to grid would suffice.

: So, basically, I want to be able to plug a QRP rig into the PA, tune up the
: QRP rig and the plate circuit of PA, and that's it.

As far as I could tell from communications with General Cement, it was FEDERAL REGULATIONS that was the issue. GC already had over a hundred products in its catalog so they weren't going to suffer any real loss in income. They've been making 'radio' chemical products for over 75 years.

>Did you by any chance try some old style enameled wire in your
>experiment above?

"Experiment?" The only experimentation I did was well AFTER my last bottle of Strip-X was used up, residue dried out. Strip-X from GC worked for me the first time I tried it long, long ago. That experimentation I wrote about was to find a possible substitute for GC Strip-X.

GC Strip-X has worked on enamel-coated magnet wire, PolythermalEze (a trade name), different kinds of wire-wrap wire. It didn't work on the surplus Teflon-coated #25 AWG magnet wire I got surplus from a transformer maker (#25 is an odd gauge, heh heh, but the transformer makers use practically every gauge in the AWG table). Tetrafluouroethylene is pretty inert stuff so few chemicals will affect it. Teflon also abrades easily compared to other insulations so it is relatively easy to strip with a knife.

>   The acetone issue is a strange one. Acetone is one of the safer
>solvents out there, heck our body even produces some acetone.

I think that should be 'acetyls' in the human body, not acetone per se. <shrug>

Acetone won't strip off enamels or other polymers used on magnet wire. I tried that, too, also toluene.

Acetone as a solvent was dropped from the model hobby industry chemicals once gas-powered models started using "hot fuel," the methanol-based stuff for glow plug engines that took over from real spark plug ignition model gas engines in the late 1940s. Methanol softened acetate-based paints, whereas the 'ordinary' gasoline used in spark ignition engine fuel did not affect acetone-solvent lacquer commonly called "dope" in model hobby industry jargon. For years Testor Chemical Company, also in Rockford, IL, had lacquer paint bottle labels of DOPE in all-capitals, something you just CANNOT DO in today's restrictive society. Building model airplanes was fun, the "dope" smelled very nice, so the blue-noses made all kinds of bad noises about the "evils" of having fun in a hobby. Sigh.

Digression: The first small two-cycle gasoline engines used real spark plugs of very small size. I still have two Champion brand spark plugs in a storage area...less than a half-inch long...and those are for the big class C and D engine displacements. I learned to solder wires properly by making the spark ignition packages for gas-powered models. The "spark coil" for those was a tiny one that was picked up by the first electronic flash units for camera use in the 1950s...ideal for igniting the Xenon flash tubes that replaced the one-shot photoflash bulbs.

Yes, I was emitting "spark" RF in the late 1940s with those spark-ignition engines, all without being licensed to do so. So were other gas-engine modelers and just about EVERY running automobile of that time! :-)

>
>That is an understatement1 8^) I have to make sure I am in a good mood,
>and no coffee for me that day before I attempt that sort of thing.

Coffee calms me down. Always has. Makes for good moods. :-)

Actually, I use a fine emery finishing paper to strip fine gauges of enamel-coated wire. I've used X-Acto hobby knives for the heavier gauges. Emery paper (easy to get at do-it-yourself stores) allows a gentle stroking of a folded emery paper over the wire. I find it works better to draw the emery paper over the wire rather than pulling the wire through the paper. Less nicking than with a knife blade for #28 to #34. I just finished a few small toroid inductors using #34 enamel-covered last week. Not recommended for beginners. :-)

PATIENCE (in all-caps) is needed to make toroids of the T37 size (about 3/8" OD), drawing a very-carefully-folded wire bundle through the center hole in a toroid core. :-) THAT is the "Zen" thing. Good self-control is absolutely necessary, can't use slap-dash hurry-up behavior.

By the way, don't use "Q-Dope" for coating finished inductors, any type. Despite what the ads say, it does NOT enhance the coil's Q. Trials of before-after measurements on a Q-Meter haven't shown goodness. ALL coatings degrade inductor Q. I've found that oil-based 'maritime' clear varnish to result in less degredation of Q than other coatings. I've used McCloskey "Gym-Seal" brand with good success on making inductor coatings that adhere to windings for years. It is available nationally in do-it-yourself stores.

Q-Dope (originally acetate-solvent based, now probably using toluene solvent) will "lift" from smooth surfaces within a year in climates with only moderate humidity. Q-Dope only adheres well to all-polymer-based surfaces, won't get into fine pores. 'Maritime' varnishes NOT polyurethane based DO grab porous surfaces. I've tried various polyurethane-based varnishes with mixed results; the makers of those apparently have a rather large variation of ingredients. Varnishes take 2, 3 days to properly cure if used on coils. That's the down-side of using the stuff in hobby applications. However, on a Q-Meter the characteristics of 'maritime' varnish coated inductors don't change much after it has reached a tacky state, roughly 12 hours after application. It ain't for 'weekender' projects started on a Saturday and 'finished' on Sunday.

73, Len AF6AY

Same idea but I use an alcohol burner like the ones that used to come
in chemistry sets. Those burners are incredably useul. Combined with a
blowpipe you can melt glass and braze small parts.

Jimmie

Paul,

Check this web site out. Perhaps these schematics, will give you better
idea what's going on.

Omer

Ooooh, he has a Breting 9. I have one of those at the shop I
need to recap and make work again.

Jeff

What about a plain old modulator?
They make some decent frequency agile ones for whole-house distribution

and whatnot,some have up to ~1W of output. (CATV modulators)

```

Agreed.

> OTOH, the little bottle of Strip-X with it's foul stench is probably not
> going to cause anyone harm outside of self inflicted (i.e. suicide
> attempts)

But it *is* dangerous stuff, and should have adequate warnings,
shouldn't it?

What does

"do-gooder done did too much with all those warnings and
attempts to protect us all from everything."

really mean? Are there too many warnings on dangerous chemicals?

More important, do we really *know* that Strip-X isn't going to cause
anyone harm unless intentionally abused?

Did every user of the stuff do so in a "well-ventilated area"? I think
not.

> Of course, I'm not so sure if Strip-X was discontinued

AFAIK, it worked on all enameled wire. Teflon isn't an "enamel".

Depending on the manufacturing process. The history of industry is full of examples of people being slowly killed at work by exposure to hazards. Asbestos, radium paint, carbon tet, MEK, all sorts of wonderful stuff.

The fact that something doesn't kill everyone who gets near it doesn't make it safe enough.

> My main point is that while we might not get much
> exposure, those who produce it just might be getting
> serious contact with nasty chemicals.

'zactly.

It's all about avoidable risk.

Another example:

Once upon a time, cars had single main hydraulic brake systems. The master cylinder had one pump that fed all four wheel cylinders.

It was simple and effective, but a failure anywhere in the system (wheel cylinder, master cylinder, brake lines, etc.) meant total hydraulic brake system failure.

Then the "do-gooders" pushed for dual brake systems, on the theory that most single failures would leave half the brake system working, plus a warning system.

Critics said that the cost and complexity were too much, and that complete brake failure was very rare in then-modern cars with single systems.

The "do-gooders" won, and dual brake systems with warnings became the standard.

Was that excessive? I guess it depends on whether you've ever had the brake pedal go right to the floor at a critical moment.

The best product for stripping enamel wire is one which not many
hobbyists will have around the home: a solder pot.

Foster Transformer in Cincinnati used this method for stripping enamel
and tinning the ends of transformer leads simultaneously. All they did
was do straighten out the leads and dip the wire ends into the pot for
about five seconds.

Yup. I've used them.

Of course someone might protest that the discussion is about doing the
job *chemically*....

bout five seconds.

Pretty much standard in the electronics industry, really. Faster and
less costly than Strip-X for production work.

At Southgate Radio, for multiple units, an improvised solder pot is
made by heating a cleaned-out tuna can full of solder splashes over a
propane torch or stove burner(with appropriate safety precautions).
For small jobs, a blob of solder on the 100 watt American Beauty iron
does the job.

Elecraft transceiver kits (except the K3) require that you wind
toroids and strip the wire ends. They recommend the solder-blob
method, and since the wire is relatively small you don't need a big
iron. My military-surplus Weller WCTPK kit does the job very well.

Chemically-schmemically. Do they want to remove enamel or discuss
semantics?

I think I've already related the tale in r.r.a.p. that I had the
President of Ideal Tool make a call on Foster with me. His plan was to
sell one of the company's new abrasive stone type enamel removing
machines. After the kindly chief engineer showed how Foster
removed/tinned with the solder pot, the man from Ideal told me that he
didn't believe there was much of a market for his machine.

Waste not, want not. I think I'd just wait until the XYL isn't home and
heat the can on a burner of the gas stove. Doesn't it sound like
something which could go terribly, terribly wrong?

I've often used a razor blade or X-acto knife to get the job done.

There's my magnitude issue. I'm in no way implying that there be no
warning on the bottles. I am implying that it is a useful product, and
legislating it out of existence, or just making it too much trouble for
a company to produce is not a good thing.

We do have a system that is pretty good. The MSDS reports are pretty
slick and non-sensational.

Of course, they won't fit on that little bottle! 8^)

I'd rather read that than something about what "The state of California
knows" you know, those strange postings beside gasoline pumps? This
product is know to the State of California as a carcinogen" type stuff.

I wonder how many people called up the state of California to talk about
that?

> What does "do-gooder done did too much with all those warnings and
> attempts to protect us all from everything."
> really mean? Are there too many warnings on dangerous chemicals?

I don't mind the warnings too much as long as they are not stupid
warnings. What I do mind is when a useful product goes away.

> More important, do we really *know* that Strip-X isn't going to cause
> anyone harm unless intentionally abused?

Or salted codfish for that matter? I know that sounds a little
sarcastic, but the point is that there is a statistical correlation
between large consumption of salted and smoked fish with stomach cancer.

> Did every user of the stuff do so in a "well-ventilated area"? I think

For me at least, the comparison of mechanical with chemical issues is a little hard to work. I have long advocated such radical technology as strong roll cages, 5 point seat belts and fire suppression systems on automobiles if we want to get serious about safety.

On the other hand, I've silvered my telescope mirrors in my garage. This involves a litany of nasty stuff, from Silver nitrate to potassium hydroxide to nitric acid. (now that stuff is scary) And oddly enough, sucrose and citric acid. I'd hate to be not allowed to do such things because someone thought I might get hurt.

Never thought of it one way or the other. I suppose if I had to classify
it as something, I'de callit chemical. But I don't get why that would be
a complaint about th eprocess.

Yes it does. I did have the occasion to melt some lead for a
counterbalance for a telescope I made. I took a cast iron saucepan and
put the lead in it, and melted it over a Coleman stove outside the
garage. I was a little concerned while I did it, but it all turned okay.

I wonder if there is a specific metal the solder pots used. I don't know
if critical applications would have an issue with contamination or not.
Solder is a bit corrosive.

Some folks will argue just for the sake of arguing. And while they will talk a lot about their experience of decades past, they'll not say much about what they have actually done recently. Particularly in terms of actually building their own ham rigs or operating on the ham bands.

That's a key value at Southgate Radio. Also:

Use it up, wear it out
Make it do, or do without

>=C2=A0I think I'd just wait until the XYL isn't home and
> heat the can on a burner of the gas stove.

That's what I described.

> =C2=A0Doesn't it sound like
> something which could go terribly, terribly wrong?

Not with "appropriate safety precautions".

Me too, but it depends on whether a tinned wire is wanted.

Now when it comes to terminating a 37 conductor #14 Kerite cable...but that's another story....

Better than voting Republican where you still pay the price, your
children and grandchildren continue to pay the price, and all the
protections go away under the guise of 'we big, rich business types have
to be able to make a profit!'

I probably should have mentioned that there is nothing special about Tower. They happen to come to all the nearby hamfests, so I've seen their stuff. I'm sure there is some sort of equivalent place everywhere else, just that Tower happens to be prominent in the upper midwest. (And they are usually at Dayton).

>
> Tim.

There are BOTH beam power pentodes and tetrodes.

RCA used to show the beam power tube with the symbol for the beam deflection plates, but later they got lazy and just drew a third grid. If you actually broke the tube open you WOULD see a 'cage' instead of a third grid.

Most beam power tubes used as AF power amps were "Pentodes", assuming you count the beam deflection 'cage' as one of the elements. Such tubes would have 5 elements making them Pentodes. It wouldn't matter if this cage was connected to the cathode or to it's own pin, it's still a pentode.

Other special beam power tubes actually did NOT have a 5th element. They had the turns of the first two grids aligned, and the spacing between the grids and the screen grid and the plate were set to minimize secondary emission. In addition, the plates had curved pockets in them designed to enhance the capture of electrons to prevent any secondary emission from ever reaching the screen grid. Tubes such as the 4-400 and 4cx250 were examples of such beam power tetrodes.

Yeah, I was surprised when I first noticed this. Little TV IF tubes
with beam forming plates! And always drawn as a pentode and called a
pentode. Maybe somebody will make a headphone amp with 6CB6s and call
them beam power tubes. :)

Well to me, a pentode is just a tube with 5 elements. Cathode, plate
and three something-elses. Historically those were three grids, but I
don't know why the 3rd element has to be a grid.

>
> And as far as people calling them beam power pentode, unless they actually=
>

a
> beam power pentode.

I think the descriptor "beam power" is similar to "sharp cutoff" or
"remote cutoff". A remote cutoff pentode isn't a pentode with an
extra element, but a pentode about which the description gives
additional information. Same with beam power pentode. But "beam
power tetrode" is much more common. So just listen up to the "beam"
word and then ignore the rest.

>
> Is it just a big international conspiracy to confuse me?

Hadn't thought about that before, but I think you're probably
right. :)

Hello,

I'm willing to make a noise source from an UHF transistor (B-E
junction reverse polarized like a zener) and I was wondering if it's
ok to use the output attenuator as part of the resistor network for
the DC bias of the transistor (or zener). I'd probably look at the
arrl handbook if I had it ;-)
Thanks
Francesco IZ8DWF

Depending on how you do it, the noise can degrade over time.  You are
better off using a diode.  My recollection is that a true zener (around
3V) works best.  I worked on an HP instrument that was originally
designed with a reverse biased transistor as a noise source.  The noise
spectrum degraded over time and caused a lot of warranty returns.  I
replaced it with a diode, and all was well.  This was 30 years ago, so I
don't remember the details.  This was for a low frequency noise source,
and things may behave differently for an RF source.

I would think that your biasing of the resistor network would create
some amount of noise which of course would not be attenuated to the same
extent as the semiconductor. But then again it may be negligeable.

Why not build it and try it out?

This coming Sunday....
the Season's First.... FLEA at MIT

****
****

Summary: Buy Sell SWAP   Ham Radio   Electronics Computers   9AM - 2PM

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

<FF>
********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 18th 2008
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take place on the third Sunday of each month this summer, April thru October.

There is tailgate space for over 600 sellers and free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if you're lucky enough to have a copy of our ad) and sellers spaces are $20 for the first and $15 for each additional at the gate.

The flea will be held on Albany between Mass Ave and Main streets in Cambridge; right in the Kendall Square area from 9AM to 2PM, with sellers set-up time starting at 7AM.

SEASON PASS + Advance Seller Discount

A sellers discount season pass is available which offers a 30% discount. By prepaying you get a discount and earlier admission. See the registration form.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered well illuminated tailgate area is available for all sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776 (M-F 9-5)

********** $1 buyers discount with hard copy of this notice ************

<FF>

Mail the coupon below by the 5th of the April to be a Prepaid Vendor.

FLEA at MIT 2008 Rates

SELLERS

To use your prepaid spaces the named vendor MUST be present.
Rates include one admission per space.

Season Pass	Sellers admission to all seven meets this year $99 First Space $70 Each Additional space Must be received by April 20th.
Advance	$17 First space $12 Additional Spaces Must be received by the 10th of the month.
Gate Admission	$20 First Space $15 Additional Spaces Admission is after the prepaid vendors.

```
Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
                ** You may not sell. **
                $15 per person at the gate.
                $70 Season Early Bird Buyer

   cut and return

well, indeed it would raise the termal noise of the resistor network,
but we are talking about less than 1 mA currents and the noise from
the source will be by far superior. I was more concerned about adding
some DC to the output, I might just try building it, but I was trying
to be sure about possible implications before beeing happy with a
result :-)

Thanks

I am not sure why you would want to do this, your parts count would at most be reduced by one resistor, you still need to have a DC blocking capacitor somewhere. Or are you using a bias "T" that is already part of the set up?

I built a noise source several years ago biasing the doide through the
potentiometer I was using for a level control and taking the noise off of
the wiper. The potentiometer was noisier than the diode.
Biased carbon resistors be pretty noisy so I reccomend using metal film
resistors.

Jimmie

Just received this through a ARES reflector

=============================

""Strong earthquake hits China, all ham radio operators stand by PLEASE HELP TO SPREAD THE FOLLOWING MESSAGE

Strong earthquake hits China, all ham radio operators stand by A Magnitude 7.8 earthquake hits Sichuan, China on Monday, May 12, 2008 at 06:28:04 UTC. Casualties and loss unknown up to now. According to Chinese Radio Sports Association, 14.270Mhz, 7.050 and 7.060 Mhz are preserved for amateur radio emergency service in the rescue. Please spread this message as far as you can and keep the frequencies clean for emergency use. Thank you.

Yesterday, 05:57 PM
BG8AAS from Chengdu, Sichuan reported that local UHF repeater survived in the disaster. It keeps functioning from the 1st minute and more than 200 local radio hams are now on that repeater. A group of hams from Chengdu has headed for Wenchuan, the center of the quake, trying to setup emergency communication services there.

BA8AB, also from Chengdu, Sichuan, is active on the 40m emergency frequency. Up to now, no further information available from the center zone of the quake. There are a few radio amateurs there, but all of the communications have been cut out, including amateur radio.

Yesterday, 06:58 PM
Update

According to BG8AAS, local UHF repeater in Chengdu keeps busy running after the quake. It helps to direct social vehicles to transport the wounded from Dujiangyan, Beichuan, and other regions. Another UHF repeater also starts its working in Mianyan, supported by generators.
However, they are going to face a shortage of gas.

Damage in Chengdu remains in the lowest level, but the situation is very

very bad in the counties around. A few towns are said to be destroyed completely. More than 7000 died in the town of Beichuan. Casualties in several other towns are still unknown and not counted in the published numbers.

It is a long and sad day.

Today, 08:31 AM
Your attention please! 14.270Mhz is now reserved for ARES in 5.12 earth quake in Sichuan, China. Please help to keep this frequency clear.

A group of radio amateurs is now transmitting from Wenchuan, the center of quake. Its signal is reported to be very weak. They tried to keep communication with BY8AA in Chengdu, seeking for all resources needed. During a contact finished a few minutes ago, they were asking for raincoats, water, tents, and outdoor living facilities.

PLEASE HELP TO FORWARD THIS MESSAGE TO ALL RELEVANT FORUMS, MAILING LISTS, AND NEWS RESOURCES. MEANWHILE, KEEP THE ABOVE FREQUENCY CLEAN FOR EMERGENCY COMMUNICATION.

Michael Chen, BD5RV/4""

We had a thread recently on Astron power supplies and I thought I'd mention that I have an RS-35A (35 amps intermittent) for VHF brick amplifiers (main use) and I've had it for some 20 years. Recently, the PS has started to "crowbar" off on me (voltage goes to zero) and not even with high currents (maybe around 15 amps or so) and have to shut it off, wait a few seconds, and turn it back on.

I also had another different regulated fairly high current DC PS go bad long ago, in a similar way.

I'm wondering how many others of you have seen defective operation, sooner or later, or other deterioration in your high current regulated DC supplies?

And, if the overvoltage crowbar craps out, it blows up your rig? I'm thinking of going exclusively back to deep cycle marine batteries, again.

Sometimes adding a .1 or .22 uF cap on the gate of the SCR to ground
will stop nuisance crowbars. Some Astrons are more sensitive than others
in this regard. We had a similar problem with a few 50 amp Astrons in
repeater service.

Pete

====================================
The crowbar is there to NOT blow up your equipment.

However operation of a crowbar should blow a fuse fitted 'upstream' of the pass transistors.   As already explained earlier in this thread ,the crowbar should also be fitted 'upstream the pass transistors (but 'downstream' the fuse , while sensing the output voltage .

If the Astron voltage regulator would be suspect I would recommend a very simple circuit with a 7812 voltage regulator and a PNP transistor ,its output 'steering' the pass transistors .

Ref : Experimental Methods in RF Design , by W7ZOI-KK7B- W7PUA
page 1.15

Instead of the 3 legged 7812 you can also use the similar LM317 enabling output voltage adjustment
After all this is a homebrew NG

and if your really smart, you will dump the fuse, and replace it with
a Resettable Circuit Breaker, because Murphy's Law states the Crowbar
will do it's thing, ALWAYS at the worst possible moment, and the

appropriate replacement fuse will be a 5 miles drive away, at the closest. You mileage may vary.....

Unless there are other major failures, the crowbar simply puts the Astron supply into current limiting. I've had 50-amp supplies running in current limiting for days because of noise-induced SCR firing.

If the supply crowbars because a pass transistor shorted, then the crowbar location becomes a rather mute matter; and involves a bit more than fuse changing.

Pete

Just to add, I've had a lot of problems with high amperage fuses, too, in brick amplifiers and power supplies and VHF rigs with those "sexy" in-line fuse holders. Seems like the connections become corroded, resistance goes up enough that the current induces drop voltage high enough to do significant heating...etc... Sometimes I've removed those fuses completely, even in one brick amplifier (25-30 amps for a 3AG fuse!!) just soldered a jumper wire across the &%$& fuse holder. Yeah, I know, bad idea. But, all my problems went away.

Also, I had circuit breakers go bad, too. Brand new ones. Expensive ones.

KIS = keep it simple.

Well, I've had a number of occurrences where, PTT on 2 M FM rig at current well below current ratings and the output voltage goes to 0.5 or less and had to off-on cycle the main switch. Makes me mad. Gotta get back to that deep cycle 12 v battery.... They always go bad very very very slowly. Great when there is a power failure, too! ;-)

Thanks to the rest of you guys that made comments, too.

On Fri, 16 May 2008 20:48:17 -0400, A wrote:

> Just to add, I've had a lot of problems with high amperage fuses, too, in brick amplifiers and power supplies and VHF rigs with those "sexy" in-line fuse holders. Seems like the connections become corroded, resistance goes up enough that the current induces drop voltage high enough to do significant heating...etc... Sometimes I've removed those fuses completely, even in one brick amplifier (25-30 amps for a 3AG fuse!!) just soldered a jumper wire across the &%$& fuse holder. Yeah, I know, bad idea. But, all my problems went away.

If you are referring to those cheap, butt-contact, twist-and-lock cylindrical fuse holders, I'll agree! They are problematic in many instances, but especially so in high current situations.

I had no end of problems with the from-the-factory in-line fuse holder with my IC-706. The IC-706 is a poor enough performer at voltages under about 12.599999VDC, and the voltage drop across the fuse holder was often enough to drop the volts into the rig even lower than that.

(Don't even get me started about the use of a butt-contact cigarette lighter "power plug".)

I now replace that style of fuse/fuse holder with the automotive, "horse-shoe" shaped style. (I'm sure there must be a more 'formal' name for them.) You can even get them with weather proof caps for under-the-hood applications.

And, for mobile operations, you can find replacement fuses up and down the hiways and byways A WHOLE LOT EASIER than you can find the old cylindrical fuses.

Jonesy

You have stray RF in the shack. Check for intermittent connections to your
antenna. Most likely a bad shield connection inside one of the PL259
commuters or a bad ground connection.

Does anyone know where I can obtain a 240 VAC, 3000-4000 W low watt
density (20wcm2) tubular immersion element made of 304 or 316 stainless
steel or inconel. The maximum outer diameter is 18 inches.

Not likely if you've been running the gear for years and didn't touch
anything.  see my response to your second post.

Not my idea but it sounded good when I heard it: "Life's too short for
spell checkers"

Ham radio advertisement many years ago: "Life's too short for QRP" and it
was for a big amplifier.

;-)

Something like that was offered as a product on the back pages of computer magazines several years ago.

It would be easy to make, if you could tolerate a really large wall wart.

Hello all,

I am trying to muliply a 72MHz crystal oscillator to 1296 MHz. My first approach was to just make a series of X2 or X3 transistor mulipliers to get the require X18 multiplication fact. However, I have found two pieces of equipment in the junk box which just use diode multipliers. One is an old Electrophone UHF CB radio which multiplies the crystal oscillator by 17 (I think, from memory)then uses helical resonators to filter the desired harmonic. The same approach is used in an old King aircraft transponder where the 138 MHz crystal is multiplied to 960 MHz with just a diode and uses the first two stages of an interdigital mixer to get rid of unwanted harmonics.

So, the question is, which is the better approach? I just want a reasonably clean signal source to test a 1296 MHz down-converter.

The diode approach seems simpler but is it likely to contain more spurious signals than a transistor multiplier chain?

I don't know, and one thing to remember is that what was done years ago
may no longer be the solution because other things have come along.

A single stage of multiplication is of course simplest. But, if you
do it in one step, the signal may be so weak that you need stages of
amplification at the ultimate frequency. Once upon a time, frequency
limits may have made that unfeasible.

Also, if you have one stage that basically generates harmonics, and then you expect to pick off the desired frequency, that filtering may need to be much better than multiple stages. If you start with a low enough crystal frequency, the next harmonic may be too close and some of it will get through the filter on the ultimate frequency. If you have a string of multipliers, each does filtering so the next stage only has to deal with filtering out a relatively high frequency.

Note that your two examples aren't comparable. The first example you say multiplies by 17, while the second only multiplies by 6. Even in the old days, it wasn't uncommon to see a jump like 6, but something like 17 was less common.

The real trick seems to be to start with as high a frequency as possible. Then the multiplication needed is limited, and it's far easier to filter out harmonics from a higher frequency crystal than a lower one.

Are you building tens of thousands like Electrophone and King did?
There was more than 'good' engineering involved with those boxes.
The bean counters were all over it, too -- I'm sure.

Sounds like a step recovery diode (SRD) multiplier, which generates a
very broad spectrum. In extreme multiplication situations a tunable

harmonic analyser could be used to select out a single harmonic from the broad SRD spectrum (mix down with a VFO, filter with a crystal filter with bandwidth comparable to the fundamental and mix up the filtered harmonic up to the original frequency using the _same_ VFO, effectively canceling out any VFO drift).

However, since there have been prescalers available for quite a while for satellite-TV indoor units, which are capable of at least 2 GHz, why not use a PLL. Put a VCO at 1296 MHz, use a divide it by 64 using the prescaler and phase lock it to a 20.25 MHz crystal. With such high reference frequency, the loop filter can be quite broad, greatly attenuating the VCO phase noise.
